# THE ENCYCLOPÆDIA BRITANNICA

## VOLUME 31

### THE THIRD OF THE THREE NEW VOLUMES PACIFIC TO ZUYDER ZEE

**PACIFIC, COMMAND OF THE** (*see* 20.434).—From the close of the Far Eastern conflict of 1904-5 to the outbreak of the World War, nine years later, strategical conditions in the Pacific Ocean were undisturbed by any development of consequence. Over the northwestern quarter of that ocean the collapse of Russian sea power had left Japan in undisputed mastery. Southward from Kamchatka to the Philippine archipelago there was scarcely a point at which she could not have deployed her navy in full force, since almost everywhere along this route of thousands of miles her ships would have found base facilities within their reach. The Russian Pacific Fleet had been destroyed, nor could it be replaced within the calculable future.

Great Britain, knowing her interests to be safeguarded by the alliance with Japan, reduced her force on the China Station to a mere cruiser squadron. Germany, it is true, continued to strengthen the defences of Tsingtao, the naval fortress of Kiaochow which served as a refuge for her small Asiatic fleet; but in view of Japan's supremacy in armament it was clear that this German outpost in Shantung did not materially affect the strategic situation. At Manila in the Philippines the United States kept a few secondary ships of war, but took no steps to develop the naval resources of this fine harbour. Guam, an American island of the Marianas group, lying 1,500 m. to the west of the Philippines, ranked only as a fuel station, though its position invested it with unique strategic value.

*Conditions After the War.*—Such, then, were the conditions prevailing in 1914. The Far Eastern seas, which had long been the arena of conflicting claims to supremacy, had now passed definitely, and, as it seemed, permanently, under the control of a single Power. Subsequent events have tended to consolidate the strategic predominance of the Japanese Empire. The conquest of Tsingtao early in the World War eliminated the only German stronghold in the Pacific. Domestic convulsions in Russia, by apparently reducing the naval forces of that State to impotence, have rendered still more remote the prospect of Vladivostok again becoming the headquarters of a formidable fleet. The Treaty of Versailles and the agreements reached at the Washington Conference (*q.v.*) have a direct bearing on the naval problems of the Pacific. Under the Versailles Treaty, the former German islands north of the Equator passed into the custody of Japan, while those south of the Equator were transferred to the British Empire. The League of Nations mandate forbids the use of these islands for warlike purposes, and does not permit of their being fortified. None the less, they constitute an important element from the naval point of view. This will be made clear on reference to a chart of the Pacific.

*Radius of Fleet Action.*—In that vast expanse of ocean every problem of strategy is fundamentally a question of base facilities. Modern fighting ships have a narrow radius of action, dimensioned by their relatively meagre fuel capacity. In time of war individual cruisers may roam the sea for weeks, even for months, at a stretch, replenishing their bunkers as opportunity offers. This, however, is not possible for an organised fleet, attended by the smaller craft which are essential as watch-dogs to the heavy ships. From experience gained in the World War it is estimated that a battle fleet, with its proper complement of ancillary units can remain at sea under war conditions not longer than four days. This does not mean, however, that such a fleet would be free to conduct operations at some point four days' distant from its nearest base, to which, accordingly, it must return for fresh supplies of fuel. To be within reach of attack the objective must not be farther away than two days' travel at ordinary speed. Special circumstances might permit of a longer sojourn at sea, but to all intents a battle fleet within the war zone is restricted to a cruise of 96 hours. With this essential fact borne in mind, the intimate relationship between strategy and geography requires no demonstration.

*Potential Naval Bases.*—In consequence of recent international negotiations, the number of potential naval bases in the Pacific has been substantially increased, with the result that squadrons, if not whole fleets, may henceforth be able to operate in waters which formerly lay beyond their reach. It is true that a great many of these islands are mere atolls, affording little or no shelter for large vessels and lacking even the most rudimentary naval resources; yet some could be used as emergency bases and fuelling stations, for which reason their existence cannot be ignored. Students of naval history need no reminder of the important part that was played in the South Atlantic operations of the British Fleet during the World War by the remote coaling base at Abrolhos Rocks, off the Brazil coast. Since 1919 Japan has exercised mandatory powers over several island groups situated far out in the Pacific. Strategically, her most important acquisitions are the Peleliu Islands (500 m. east of the Philippines); the Carolines; the Marianas Islands, excepting Guam, which is American territory; and the Marshall group, these latter being some 1,700 m. to the southwest of Hawaii. Light naval vessels, aircraft and submarines, judiciously distributed among the islands named, would represent a serious menace to a hostile force advancing towards Japan from the east. So much for the reaction of the Versailles Treaty on Pacific strategy.

*The Washington Treaty.*—Of equal significance in the same connection is the Five-Power Treaty concluded at Washington

in Feb. 1922. This covenant has not only reduced very considerably the battle fleets of the leading naval powers, but has in some degree nullified the effect of the territorial changes in the Pacific for which the Versailles Treaty was responsible. Under the Washington Treaty the British Empire, the United States and Japan agreed to maintain the *status quo* as to fortifications and naval bases in a series of highly important strategic positions in the Pacific. The United States, for example, is pledged not to improve in any way the shore defences or naval works in the Philippines, Guam or the Aleutian Islands; Japan accepts the like obligation in regard to the Bonin Islands, Formosa and other insular possessions; while the British Empire is debarred from adding to the naval resources of Hongkong. Since the zone to which this agreement applies begins east of the meridian of 170° east long, Singapore lies beyond it, and is therefore not affected.

The Hawaiian Islands are also exempted, though they are more than 2,000 m. from the American mainland. Their position makes them invaluable as the pivoting centre of a fleet charged with the task of defending not only the western seaboard of the United States, but the outlying territories of Alaska and Samoa. Despite its capital importance as a strategic focal point, Hawaii has yet to be adequately developed as a fleet headquarters. In 1925 the naval base at Pearl Harbour, near Honolulu, was not accessible to the heaviest battleships in ordinary conditions of tide, nor could it be approached at all by battleships whose normal draught had been increased through damage or other cause. Extensive dredging operations are projected to remedy this state of affairs, and the building of new docks, magazines, etc., is contemplated. Singapore, like Hawaii, is mainly, if not entirely, a defensive factor in the general problem of Pacific strategy. First utilised as a naval harbour in 1882, it has been for many years the southern base of the British China Squadron. The new dockyard begun in 1924-5, is designed to meet the requirements of a battle fleet, the presence of which at Singapore would doubtless be an indirect but none the less effectual deterrent to plans for the invasion of Australia or New Zealand.

**Conclusions.**—Broadly speaking, no single Power or combination of Powers could ever aspire to command so enormous an area of sea as the Pacific Ocean. The most that can be done by any State which has a vital interest—whether territorial or economic—in the Pacific is to take appropriate measures for maintaining the integrity of its particular sphere of influence. So long as warships are as dependent upon shore communications as is now the case, overseas naval operations on a major scale within the limits of that ocean would probably entail an expenditure of force which, if not altogether prohibitive, would be out of proportion to the object in view. Although the United States and Japan both maintain imposing fleets in the Pacific, and the British Empire may eventually have a considerable force available in the southern area, it is difficult to see how any one of these Powers, or even two Powers acting in concert, could dominate more than a relatively small sector of an ocean that extends from the Arctic to the Antarctic regions, is 10,000 m. across at its greatest breadth and covers nearly one-half of the entire surface of the earth. (See also SINGAPORE; WASHINGTON CONFERENCE, etc.)

**PACIFIC ISLANDS:** see OCEANIA.

**PADEREWSKI, IGNACE JAN** (1860- ), Polish pianist and statesman (see 20.443), with characteristic generosity created the Paderewski Fund in 1900, the object of which was to encourage American composers by offering prizes for composition. His unprecedented success as a pianist all over the world never caused him to forget his own country, and to the Poles in America he delivered the following inspiring message: "The

vision of a strong and independent Poland has always been the lodestar of my existence. Its realisation is still the great aim of my life." In 1910, when his compatriots were celebrating the 500th anniversary of the victory of Grünwald over the Teutonic knights, he presented them with a magnificent gift in the shape of a memorial which was unveiled at Cracow in the presence of representatives from all parts of Poland. In 1911 the University of Lemberg bestowed on him the degree of doctor of philosophy, *honoris causa*.

When the World War broke out in 1914, his chief desire was to work for his country, to whose service he dedicated his encyclopaedic knowledge, his unfailing memory, his power of work, his eloquence and prestige, as well as his powerful connections in both hemispheres. He was president d'honneur of a non-party group of Poles who met at Vevey in the autumn of 1914 to organise a "General Committee of Assistance for the victims of the War in Poland." The Committee was definitely founded in Jan. 1915 under the presidency of the great novelist, Sienkiewicz. M. Paderewski established branches in Paris and London; he then proceeded to the United States, there to co-ordinate the work of the 4,000,000 Poles who had formed a "central committee of assistance" and who were in touch with the Vevey committee. On his arrival, he called on his countrymen to stand together, informing them that he belonged to no party and came only to stretch out his hand "as a beggar." He remained nearly four years in the United States, giving numerous concerts and making speeches in order to collect funds and enlist public opinion in America in the cause of Poland. He not only collected enormous sums, but created a pro-Polish movement in the United States, which developed with amazing rapidity.

As honorary president of the Polish National Department of Chicago, and as the friend of President Wilson and Colonel House, M. Paderewski exercised an increasing influence in the political circles of Washington, with the result that President Wilson on Jan. 22 1917 alluded to a "united, independent and autonomous Poland." Not only Poland, but all the Allies, had reason to be grateful to M. Paderewski for his services, and it was said of him that "his propaganda and eloquence contributed largely to the enthusiasm with which the citizens of the great American republic threw themselves into the formidable struggle against Germany." Though he had to fight unaided, with only his personal resources, against the formidable propaganda of the Central Powers, he was completely successful; for by Nov. 1916 every Polish organisation in the U.S.A. was represented in the Polish National Department of Chicago, except the small Socialist group. For more than two years, up to 1918, M. Paderewski guided the political and military destinies of 4,000,000 individuals. On the day after the notorious manifesto of the Austro-Hungarian and German Emperors of Nov. 5 1916, promising the establishment of a Kingdom of Poland, he drew up a declaration of protest which was signed by many eminent Poles who felt that the offer was a perfidious one.

Foreseeing in Feb. 1917 that the U.S.A. would soon enter the War, M. Paderewski induced the Polish National Alliance to found a preparatory school for Polish officers at Cambridge Springs. It was, however, only after the decree which authorised a Polish army to be raised in France that M. Paderewski succeeded in Nov. 1917 in obtaining from that wise and generous statesman, Newton Baker, permission to recruit volunteers. He took a most active part in the recruiting, maintaining enthusiasm by numerous speeches. With the aid of the British Govt. he succeeded in obtaining from the Canadian Govt. a vast military camp, Niagara on the Lake, where more than 22,000 Polish volunteers were trained by Canadian officers. In Aug. 1917 the Polish National Committee, founded at Lausanne, chose M. Paderewski as its representative to the Washington Govt., and it was in consequence of representations made by him that Mr. Lansing officially recognised the committee.

After the victory of the Allies, M. Paderewski by no means considered his task at an end. He arrived in London in Dec. 1918, and was cordially received by British statesmen. Mr.

Balfour and Mr. Lloyd George placed the cruiser "Concord" and several torpedo-boats at his disposal, and he proceeded to Poland by sea in the company of a British Mission under Colonel Wade. He disembarked at Danzig on Dec. 24 1918. His popularity was already immense; and on arriving at Posen on the 26th he was welcomed with indescribable enthusiasm, although the German soldiers fired on the buildings in which he was staying. At Warsaw he was acclaimed by over 100,000 persons. He declared himself independent of all political parties; and after difficult negotiations, during which an attempt was made on his life, he succeeded on Jan. 17 1919 in forming a coalition ministry, of which he became Prime Minister as well as Minister of Foreign Affairs. He obtained for Poland official recognition by the various Powers, and thus regularised her international situation. The existence of various military groups named after their respective leaders seemed an obstacle to national unity, so M. Paderewski decided to suppress them, and at the first meeting of the Diet he demanded that a national army be formed. In spite of opposition this demand was granted.

M. Paderewski was always treated with special goodwill by the British Govt., which at his request sent over capable instructors to organise the Polish national police. As Prime Minister and Minister of Foreign Affairs he went to Paris on April 6 1919 as Poland's first delegate to the Peace Conference. His efforts were successful, and he returned to Poland in May and again in July, to reassure the doubtful and to preach, as before, the doctrine of conciliation. On two different occasions, on May 23 and July 31, the Diet renewed its vote of confidence in him and expressed the gratitude of his country. But as it was impossible for him to make a National Union a reality, and, above all, to conclude peace with the Soviet Govt., in view of the violent opposition of the military party, he decided to resign office (Nov. 27 1919). Deepest regret was expressed at his resignation; and his name was proposed for the presidency of the republic, but he preferred to stand aside. He defended the interests of his country, however, at the Conference of Ambassadors and before the League of Nations, where his generosity and pacific spirit were fully appreciated.

Though desiring conciliation, he could not in Poland's name accept the decision of the Conference of Ambassadors regarding Teschen in July 1920 without raising a solemn protest against the conduct of Czechoslovakia in this connection. While dealing with the question of Danzig and the relations between Poland and Lithuania at the League of Nations, he realised that a certain section of opinion was hostile to him; he therefore decided to abandon his political career in Feb. 1921, and retired to his Californian estate, returning afterwards to resume his musical career. His many distinctions include the Grand Cross of the Order of Leopold of Belgium and the Grand Cross of the Order of the British Empire. (H. GN.)

**PAGE, THOMAS NELSON** (1853-1922), American author and diplomatist (see 20.450), was appointed ambassador to Italy by President Wilson in April 1913. In 1914 he announced his discovery of the house, 66 Piazza di Spragna, in which Byron had lived at Rome in 1817. In 1915 he induced the Italian Govt. to raise the ban on the re-exportation of cotton goods dispatched by American shippers via Italy to other countries. He earned the gratitude of the Italians by his relief work during the Avezzano earthquake in 1917. He resigned the ambassadorship in April 1918 and returned to America, dying at Oakland, Va., Nov. 1 1922.

Page's later writings included *Robert E. Lee, Man and Soldier* (1911); *The Land of the Spirit* (1913); *Tommaso Jefferson, Apostolo della Libertà* (1918; prepared for an Italian series); *Italy's Relation to the War* (1920); *Italy and the World War* (1920) and *Dante and His Influence* (1922).

**PAGE, WALTER HINES** (1855-1918), American writer and diplomat, was born at Cary, N.C., Aug. 15 1855. His father, Allison Francis Page, was descended almost exclusively from English ancestors; his mother, Catherine Frances Raboteau, was Scotch and French Huguenot in origin. Perhaps Page's finest inheritance from his father's family was a strong devotion

to the cause of the Union, while from his mother he inherited a love of literature. From the standpoint both of mind and character; therefore, Walter Page's inheritance was a rich one; it gave him an energetic, clear-seeing brain, a predominant moral sense, a profound patriotism on national lines, a devotion to public service and a faith in education as the essential basis of the self-governing citizen. Even as a child Page displayed these qualities.

At the age of 16, in Jan. 1872, after a preparatory course at the Bingham Military School at Mebane, N.C., and a year at Trinity College, Page entered Randolph-Macon College at Ashland, Virginia. The greatest influence in his life at this time, and an influence that continued to the end—was Thomas Randolph Price, professor of Greek. Professor Price had two great enthusiasms—English and Greek literature; he became deeply attached to Page, both as a boy and as a student, and devoted much time to his training. Price made another great contribution to Page's education; for he obtained his appointment as one of the first 20 fellows of the new Johns Hopkins University at Baltimore, with the result that the young man, in Oct. 1876, found himself one of a group of five ambitious Grecians sitting at the feet of America's greatest classicist, Basil L. Gildersleeve. Page read intensively the Greek tragedians, orators, historians and philosophers, and though, in the philological sense, he never became a great Greek scholar, he did drink in a knowledge of antiquity and a feeling for Greek literature which deeply influenced all his subsequent habits of thought as well as his own literary style.

Page's health, always frail, broke down in March 1878 and he consequently left Johns Hopkins without a degree. He met much discouragement in his efforts to get a start in life. A winter (1878-9) spent teaching English at the high school at Louisville convinced him that his nature demanded an active life among men, and in 1880 he became editor of the *St. Joseph Gazette*. But a small Missouri town did not hold Page's interest long: he broke away in the summer of 1881 to make a tour of the Southern States, writing a series of brilliant articles that were simultaneously printed in several leading American newspapers—one of the first cases, if not the first, of the now familiar newspaper syndicate. The next two years Page spent as literary editor of the *New York World*, but in 1883 he resigned and returned to Raleigh, North Carolina. For two years he edited the *State Chronicle*, a weekly newspaper, as distinguished for the vivacity of its editorial style as for the unconventionality of its opinions.

Page was only 28, but he had completely reasoned views on all Southern questions. He ridiculed the current worship of Confederate officers, especially the tendency to regard a war record as almost the exclusive qualification for public office; advocated primary education for both the white and the black, the development of scientific agriculture, the building of modern highways, the creation of local industries and the lessening of ecclesiastical influence in all departments of life. All these changes North Carolina has since introduced to a degree that has given her the leadership among Southern States; the youthful Page, however, was 40 years ahead of his time, and, after two rather tempestuous years, in which he found himself denounced as a "Southern Yankee," he had to confess failure, dispose of his paper and resume his life in New York.

*His Literary Career.*—Page's opportunity came in 1887 when he joined the staff of *The Forum*, a monthly review then in serious difficulties. In four years he transformed a bankrupt property into a profitable one, and made it one of the most influential organs of public discussion in the English language. He resigned his editorship in 1895 and entered the Boston publishing house of Houghton, Mifflin and Company. For two years he was literary adviser and associate editor of *The Atlantic Monthly*, and in 1898 became editor-in-chief of that venerable New England magazine. His tenure was brief, however, for in 1899 he joined Frank N. Doubleday in establishing the publishing house of Doubleday, Page and Co., and founding *The World's Work* magazine, of which Page served as editor from 1900 to 1913. For 14 years Page led the active career of a publisher and editor, but he spent a large amount of time as lecturer and writer advocating the causes which had always been his chief interest in life.

Of these the leading one was popular education, especially in the backward South. As a member, first of the Southern Education Board and afterwards of the General Education Board, he played his part in distributing the Rockefeller millions for this purpose. His speeches were probably the most powerful influence in awakening the Southern States to their cultural shortcomings. By initiating the movement for the eradication of the hookworm, he started the work that has since taken shape in the International Health Board. He served on President Roosevelt's County Life Commission, and was a leader in introducing Dr. Seaman A. Knapp's demonstration work in agricultural areas. All these years he closely followed political affairs, and in 1911 was one of the first to proclaim the presidential qualifications of Woodrow Wilson, whom he had known for many years. One of Wilson's first acts, after his inauguration, was to appoint Page ambassador to Great Britain.

*Ambassador in London.*—For his five years in London Page's life had been a preparation. His deepest convictions—his passion for democracy, his belief that British institutions and literature formed the most solid basis of civilisation, his long advocacy of British-American co-operation as the most satisfactory method of solving world problems—were all put to the severest test in the five arduous years of his ambassadorship. He had established familiar and congenial relations with the British public and British officialdom—especially with the Foreign Secretary, Sir Edward Grey—when the World War began. Up to that time Page had also worked in complete harmony with President Wilson. Early in his London days the ambassador began writing the President his impressions of British life and British society—letters which the President greatly enjoyed and valued. It was owing mainly to his prompting that President Wilson persuaded Congress to repeal the discriminating Panama tolls. He continued this correspondence throughout the War.

In the War Page saw above all an attempt of Germany to grasp the hegemony of Europe, and to substitute the Prussian conception of autocracy for the democratic ideal which he regarded as the true path of human progress. It soon became apparent, however, that President Wilson did not then accept this interpretation of events. It was mainly this difference that caused the historic divergence between Page and Wilson. To the outside world Page maintained an attitude of strict neutrality; in his private communications to the President, however, he made no secret of his complete sympathy with the cause of the Allies, and his general disagreement with the policy of the Administration. As Washington did not grasp his view of the struggle, Page's efforts, for the first year, were ceaselessly devoted to keeping Great Britain and the United States on friendly terms. When the "Lusitania" was sunk, Page in his letters and cablegrams to Wilson strongly advocated an American declaration of war against Germany. He insisted then, as he did afterwards, that American intervention at that time would have brought the War to an early end with an Allied triumph. At all subsequent crises he kept constantly to his main argument—that the War was a life-and-death struggle between autocracy and democracy, and that the United States could determine the result in only one way, by intervention with all its military, financial and economic power. Page's great moment came on April 2 1917, when President Wilson asked Congress to declare the existence of a state of war with Germany, and in his speech used arguments that Page had been forcing on his attention for three and a half years.

Page had never been in robust health; he was not a hale man when he began his work in London in 1913, and the anxieties and labours of a terrible period gradually exhausted his physical frame. He had meditated resignation many times, and consented to remain only at the earnest request of President Wilson. In Aug. 1918, however, he became so ill that the President acquiesced in his retirement. In early Oct. he sailed on the "Olympic" and reached New York so weak that it was necessary to carry him from the ship on a stretcher. His one wish was to return to "the sandhills" of his early home in North Carolina. There he died on the evening of Dec. 21 1918, in his 64th year. He was survived by his wife (formerly Willia Alice Wilson, whom

Page married Nov. 15 1880), and by three sons and one daughter. Several memorials to his life-work have been established, of which the most important are the Page School of International Relations at Johns Hopkins University, Baltimore, Md., and a tablet erected to his memory by his British admirers in Westminster Abbey.

**BIBLIOGRAPHY.**—The chief authority on Page's career is *The Life and Letters of Walter H. Page*, by Burton J. Hendrick (2 vol., 1922; 3rd vol., 1925). *The Intimate Papers of Col. House* (2 vol., 1926) and *Twenty-Five Years* (2 vol., 1925) by Viscount Grey of Fallodon are also valuable. *The Rebuilding of Old Commonwealths* (1902) gives in eloquent language Page's aspirations for the revitalisation of the Southern States. *The Confessions of a Publisher* (1905) gives his creed on his trade. In 1909 Page also published under the name of Nicholas Worth, *The Southerner*, a novel whose main purpose was to serve as a background for preaching his favourite ideas on the South. In parts it is semi-autobiographical, but only in parts. Page's literary fame will rest on his letters. (B. J. H.)

**PAGET, VIOLET:** see LEE, VERNON.

**PAINLEVÉ, PAUL** (1863– ), French politician, was born in Paris Dec. 5 1863. He was educated at the École Normale Supérieure and became a doctor in mathematical science, soon showing himself to be a mathematician of the first rank. He became a professor at the Sorbonne, and while still quite young he was elected a member of the French *Académie des Sciences*. From the time of the Dreyfus case his interest in politics increased; in 1906 he was elected deputy for Paris, as an independent Socialist and took a special interest in all questions relating to the army, navy and air force. It was not, however, until the World War that M. Painlevé occupied a political position of any great importance. In M. Briand's cabinet, formed on Oct. 29 1915, M. Painlevé became Minister of Public Instruction and of Inventions; but finding himself in disagreement with M. Briand in regard to the conduct of the War, he ceased to be a member of the Briand Govt. when the latter was reconstructed on Dec. 12 1916.

In March 1917 M. Ribot became premier and gave the portfolio of Minister of War to M. Painlevé, who proceeded to appoint Gen. Pétain in place of Gen. Nivelle as commander-in-chief of the French Army. On the resignation of M. Ribot, M. Painlevé himself formed a cabinet on Sept. 12 1917. He would have included the Socialists in his Government, but owing to their exaggerated demands he was unable to come to an agreement with them. In addition to being premier, M. Painlevé continued to be Minister of War. On Oct. 19, in consequence of a vote of the Chamber, he felt that his majority was insufficient, and therefore resigned; but he at once reconstituted his cabinet, replacing M. Ribot by M. Barthou at the Ministry for Foreign Affairs. A few days later, after the Italian disaster at Caporetto, he went to Rapallo at the same time as Mr. Lloyd George to meet the Italian premier, Signor Orlando. These discussions resulted in the creation of the Supreme Allied Council at Versailles, Gen. Foch being chosen by M. Painlevé as the chief representative of France. On Nov. 13, the Chamber having refused to postpone questions regarding "defeatism," M. Painlevé resigned and was succeeded by M. Clemenceau.

After some years of restricted political activity, M. Painlevé with M. Herriot helped to form the *cartel des gauches*, which obtained a majority in the general elections of May 11 1924. The two heads of this group, M. Herriot and M. Painlevé, became premier and President of the Chamber respectively. The Radicals now organised a kind of ministerial strike, with the result that M. Millerand was forced to resign the Presidency of the Republic. The attempt to replace him by M. Painlevé failed, and M. Doumergue was elected President. In April 1925 M. Herriot was forced to resign after a defeat in the Senate on financial questions and M. Painlevé succeeded him as premier, taking over the portfolio of War as well. M. Caillaux became Minister of Finance, a position of special importance at that time of financial crisis.

In June M. Painlevé went by air to Morocco, where owing to the offensive of Abdel-Krim a difficult situation had arisen; later he sent out Marshal Pétain to organise resistance and

"AFTER THE BATH" BY JOAQUÍN SOROLLA Y BASTIDA

direct a counter-offensive. In July he found it was impossible to remain in power without the support of a section of the opposition, for the Socialists refused to accept the fiscal policy of M. Caillaux. In Oct., therefore, with a view to gaining the support of the extreme left, M. Painlevé himself took over the Ministry of Finance from M. Caillaux. But on Nov. 21 he found himself with a minority in the Chamber owing to his financial proposals. He was succeeded as premier by M. Briand; and, both in that Government as well as in the one formed by M. Briand in March 1926, M. Painlevé continued to hold the portfolio of War. An able mathematician, M. Painlevé was made a member of the academies of science of France, Bologna, Stockholm and Upsala as well as of the Reale Accademia dei Lincei in Rome. Among his various works on mathematics may be mentioned: *Leçons sur le frottement* (1895); and *Leçons sur la théorie analytique des équations différentielles* (1897). (P. B.)

**PAINTING** (see 20.459).—The end of the 19th century saw in painting the triumph of "impressionism" in its widest sense.<sup>1</sup> With the heterodoxy of the 19th century become the orthodoxy of the 20th, a movement developed in revolt against impressionism, giving to painting between 1900 and 1926 a distinctive character. This movement, like impressionism, is mainly French in origin, though elsewhere it has taken colour from national characteristics. But changes have been greater in appearance than reality. Impressionism is very much a living force; older academic traditions still survive and have even gained strength from a reaction against impressionism; while the practice of the rebels has paid more heed to older standards than have their doctrines.

Across these main movements cut the influence of the War. At first it threatened to limit artistic output severely, but the check was only temporary. A huge demand arose in the belligerent countries from individuals and public bodies for illustrative, propagandist or commemorative work, which bore fruit in posters and cartoons; in the formation of official collections such as those in the Imperial War Museum and in Canada; and in decorative paintings for memorial purposes. The chief interest of this work is that of a document, showing what men did, felt and thought during the War, and of giving a summary of the condition of art at the time in various countries. The aim of the British and Canadian official collections was definitely to preserve a pictorial record of the War in all its aspects, and, consequently, much of the work is primarily the skilful application of a technique to this task, and not the expression of a new vision or a personal emotion.

The same applies to most memorial decorations, and, though in all countries the posters were the work of prominent artists, their appeal was only in part æsthetic, designed as they were mainly to excite hatred, cupidity, pity and self-sacrifice. Yet by putting the production of the poster into the hands of artists, and by helping to revive and stimulate wood engraving and lithography, the War had considerable influence on the graphic arts. Otherwise, its immediate effects have been small. It has perhaps strengthened the nationalist spirit in art, as a result of a cessation of international intercourse during the War and of the creation of small independent states. It may also have given a new impulse to a search for structure and design, by reducing life so much into terms of machinery and organisation; and by the depth and variety of the emotions it aroused may have stimulated the tendency to use form and colour for the expression of personal feeling rather than for the reproduction of nature. Probably, too, by making a definite breach with 19th century ideas, the War cleared the way for the development of new æsthetic standards. But the most important modern movements in art were in being before the War.

<sup>1</sup> Unfortunately for clarity of exposition, the term "impressionists," originally applied to the group of artists round Claude Monet, painters in a high key using a palette limited to white and the spectral colours, has been extended, especially in England, to include all painters whose main aim is the reproduction of the visual appearance of a scene as a whole. In this wider sense the term is here used throughout.

## I. THE REACTION FROM IMPRESSIONISM

*The Later Impressionists.*—Of movements which attained full development in the 19th century, impressionism in its purest form is still represented in France by Claude Monet, in Belgium by Emil Claus and in Great Britain by Lucien Pissarro. Of its many developments and adaptations, the neo-impressionism, based on the analysis of colour in nature into its constituent elements, which are then placed by means of juxtaposed spots of paint upon the canvas, to be recombined by the eye, survived in 1926 only in modified form. Paul Signac, one of its original exponents, has substituted for spots brick-like rectangles in his oil paintings, and increased use of line in his water-colours. Another variation, pointillism, in which colour already mixed on the palette is applied in spots, is represented by Henri Martin and Henri le Sidaner. Paul Albert Besnard, appointed in 1924 director of the École des Beaux Arts, Paris, had adapted the impressionist analysis to deal with complicated problems of double lighting which in England have interested Charles Sims and Ambrose McEvoy in portraits and figure pieces. Jacques Émile Blanche, on the other hand, derives more directly from Manet in his bold brushwork and the simplified masses of his design.

In England, the spectral palette and high key has been only a passing phase with most painters. Wilson Steer in both portrait and landscape passed to a narrow palette including black, in work marked by much subtlety of tone and colour and great feeling for light and atmosphere. After a period of more positive colour, he returned in his latest work to a limited range of browns, greys, blues and greens, and a simplified direct handling analogous to that of water-colour. George Clausen, once the leading disciple of Bastien-Lepage in England, has interested himself in mural work, and gives increasing attention to design in his sensitive interpretations of misty, sunlit landscape.

Study of tone and design based on silhouette gives a common basis to members of the Glasgow school, such as Sir James Guthrie, E. A. Walton (1860-1923), Sir John Lavery and D. Y. Cameron. These served as starting-point for Sir William Orpen, combined in later work with vivid colour used decoratively, ingenious use of double lighting, and a strong bent for satire and caricature. The death of J. S. Sargent in April 1925 removed an outstanding figure, witness to whose reputation was the remarkable total (£182,585) realised by a two-days' sale in July of part of the contents of his studio. Vivid realisation of external aspect by singularly direct and forcible means, based on impressionist practice, was his peculiar power. This was best displayed in portraiture and landscape; a series of mural decorations in the Boston Museum of Fine Arts, completed just before his death, consisting of mythological scenes executed in golden ochre on a blue ground, are accomplished but lifeless. Of the group of painters who, under the influence of Millet and Bastien-Lepage, carried the realism of Courbet and Manet into the field and workshop, the chief survivors in 1926 were Lucien Simon and Charles Cottet in France, Max Liebermann in Germany, Joaquin Sorolla in Spain and Ettore Tito in Italy. In Great Britain the once prominent Newlyn group has fallen into obscurity; in Sweden Anders Zorn, best known by his portraits and etchings, is dead; and the Hague School of Holland has no important living representative.

*Transition Painters.*—Between these representatives of impressionism in the widest sense and those of the modern movement stand many painters combining in varying degrees characteristics of both groups. Among these are the decorative painters, who have necessarily never fully accepted impressionism and realism. As early as 1892 the Rose Croix group in France had urged that painting should be idealist and monumental in character, with myth and allegory as its subject. These ideas survive, combined with impressionist influences, in the balanced and harmonious compositions of René Menard, whose descent is from Puvis de Chavannes, in the mural decorations of Henri Martin, and in the work of Amand-Jean, whose flowing arabesque and pastel tints relate him to the 18th-century decorators. Akin to these painters, but closer to the

modern movement and more purely decorative in intent, is the broadly handled work of Jules Flandrin (b. 1871). Another group of decorative painters take realism as a starting-point. Among these is Frank Brangwyn (b. 1867), one of the few English painters with considerable European influence and reputation. His later work, such as the eight mural paintings, symbolising the dynamic forms of nature, for the 1915 Panama Pacific Exposition, and the twelve panels finished in 1925 in the dome of the State House of Missouri, is dexterous and schematised in handling, and combines romantic and allegorical treatment of material drawn from the daily life of commerce and industry with a sensuous materialism.

A comparable figure is Ignacio Zuloaga (b. 1870), the leader of a group of Basque and Castilian painters, including Ramon and Valentine de Zubiaurre, Gustavo de Maeztu and Federico Beltran-Masses, who consciously aim at expressing Spanish national character in their art. With them a romantic conception of subjects drawn from contemporary Spanish life is given decorative form by emphasis on silhouette, simplification of form and broad masses of colour, often combined with a low horizon and a panoramic background; though sometimes the realism degenerates into caricature and the decorative treatment into the production of cardboard figures against a stage drop-scene.

Among British painters, Augustus John is best known by his portraits, which combine accomplished drawing and power to record, a likeness with the decorative use of broad masses of colour, considerable simplification and occasional distortion of forms. His larger subject pieces are apt to be empty and mechanical. Sir C. J. Holmes is conspicuous among landscape painters for his emphasis on structure and design; and the well-planned architectural and mountain pieces of Sydney Lee unite sombre dignity with painstaking study of detail. William Rothenstein has abandoned the low key and sombre colour of his earlier work for a decorative treatment and a more vivid palette in his later paintings. The Munich decorative school, as seen in its most important product, Franz Stuck (b. 1863), inherits from Böcklin the realistic treatment of mythological and allegorical materials. Its once important and widespread influence has waned; but it forms part of the bridge between the archaeological and historical painting which formerly dominated Germany and more modern movements. Allied to this school is the Swiss Ferdinand Hodler (1853-1918) by the emphasised contours and calculated distortions of his later work. But in his symbolic mystical outlook he resembles another important German forerunner of the modern movement, Hans von Marées (1837-87), neglected in his lifetime but, now the object of adulation, who turned from Courbet and Manet to Rubens and Delacroix in developing a grandiose decorative art.

*Degas and His Influence.*—Another important divergence from the main trend of later 19th-century art is seen in France in the art of H. G. E. Degas (1834-1917) and Pierre Auguste Renoir (1841-1919). Their close association with the impressionists was reflected in the choice of subjects from contemporary daily life, and at times in their use of colour. But Degas mainly descends from the great draughtsmen of France. A convinced realist, bitterly opposed to the romantic and symbolic, he never sought the ideal beauty of Ingres, but turned to use the more absurd and bizarre attitudes of everyday life. His realism is synthetic, and represents the building-up, from many sketches and from a retentive memory, of the essential character of a form or movement; and his vision is classic in its impersonal, almost ironic quality. So with his design, which, despite its apparent disregard of the rules of classical composition, yet shows a complete balance of strains and stresses round a pictorial centre, revealing the influence of Chinese and Japanese art. Round Degas centres a group of realistic draughtsmen, such as Henri de Toulouse-Lautrec (1864-1901)—whose fevered, and excited vision inspired much modern work—Louis Legrand and J. F. Raffaelli.

Jean-Louis Forain (b. 1852), chiefly known for his political and social cartoons, has the realism and ironic spirit of Degas,

but less power of design and feeling for colour. As an etcher, however, he is in the front rank. The later work of T. A. Steinl (1859-1923), well known by his journalistic work, is significant of modern tendencies in the increased emphasis given to the third dimension and the use of simplified forms. Renoir inspired no special group which calls him master, nor was he the exponent of an aesthetic creed. His earlier work was much under impressionist influence, in its easy vivacity recalling Fragonard. Later, he grafted impressionism on to a romantic decorative manner inspired by the Venetians and Rubens, searching for increased solidity and simplicity in his forms, so disposed to give somewhat the quality of a bas-relief to his painting. Meanwhile, his colour became less naturalistic, ultimately being dominated by the famous Renoir carnation.

In Great Britain, the realism and satire of the figure subjects of Walter Sickert (b. 1860, A.R.A. 1924) are a link with Degas; also the growing breadth of treatment in his later work. He adds, however, a characteristically English humour. In landscape, his search for accurate record of tone relations and incursion into the use of the spectral palette bring him near the impressionists. His influence in transmitting French influence to several younger painters has been considerable. Henry Tonks (b. 1862), professor at the Slade School, has also done much to mould the younger generation, by his enthusiasm for drawing. As a painter, his choice of theme links him to the English painters of domestic genre; his realism and sense of humour to Hogarth; his handling of colour to the impressionists. Literary and satiric intention is uppermost in the work of M. Beerbohm but he is also notable for his delicate linear draughtsmanship and skilful design.

## II. THE MODERN MOVEMENT

*Post-Impressionism.*—The modern movement has been given various labels, such as post-impressionism and expressionism; but its manifestations are so various that no one term can satisfactorily describe it. These manifestations, however, have common origin and character, in being a reaction against impressionism, with its aim of representing visual appearance as a whole at a given time, without reference to shape or appearance as they may be known to exist under other conditions; and proposing to substitute form arranged into a coherent design, to make a new reality and not a reproduction of nature. In this certain modern painters claim to be returning to the tradition embodied in the work of Raphael, Poussin, David and Ingres, as opposed to the romantics and realists; and to be breaking away from subordination to external and visible things in order to utilise them in expressing the artist's emotions.

From this latter aspect of the movement arises the term "expressionism"; and divergence as to the kind and quality of emotion to be expressed is one cause of the differences between various modern groups. The general character of the movement helps to account for other distinctive features. Colour becomes less naturalistic, and is used to emphasise the solidity of objects; is purely decorative, or assumes a mystical and symbolic character; and anxiety to avoid a transcript of nature has stimulated return to the subject picture, which calls for constructive effort. But the modern movement owes much to the impressionists. It was they who helped to discredit the formulas and aims of academic art; put powerful weapons in the painters' hands for applying to art scientific discoveries regarding light and colour; and won recognition of the artist's freedom to express his personal vision of things. It was on this basis that the chief initiators of the movement built. These fall into two groups, the one including Cézanne, Seurat and Henri Rousseau, whose emphasis tends to be on structure and design; the other including Gauguin, Van Gogh and Gustave Moreau, in whom symbolist and expressionist elements are more marked.

*Cézanne.*—Paul Cézanne (1849-1906) gives a clue to understanding of his aims and methods by his own words, that he wished to do Poussin over again according to nature, and to make impressionism something solid and durable like the art of the museums. His sympathies were all with the later Venetian

"THE WAY DOWN TO THE SEA" BY AUGUSTUS JOHN

*This painting is one of the best known examples of the earlier work of Augustus John. It not only shows the power of his draughtsmanship, but, with its characteristic of definite contours enclosing areas of colour, relates him to the 15th Century Italian painters.*

Rubens, Poussin and the baroque masters such as the Caracci and El Greco, whose craftsmanship, bravura and well-organised design he admired. These tastes found expression throughout his life, but are most evident in his earlier work. In this he used little colour; but under the influence of the impressionists, especially Pissarro, he extended his palette considerably (though still retaining black and the earth colours) and turned to a more intimate study of nature. Contemplation of her, he held, reinforced by reflection and study of underlying causes, creates in the artist's mind a vision of the structure underlying the external, visible world, which to him becomes a series of organic relations between solid forms, which he should seek to realise on canvas. Cézanne's method was to establish the relations between the planes enclosing an object or group of objects by recording all the subtle differences in their colour due to differences in their relation to the light. But it was the form, not the light around it, which interested Cézanne. He worked slowly and painfully; and such was his desire for keeping every element of his work in correct relation that one alteration would often lead to complete repainting. The legend of Cézanne's technical incompetence is partly due to his constant self-deprecation and to the amount of work he left unfinished in despair or disgust. Though his ultimate rank as a painter is still in the balance, his influence underlies much modern painting.

*Seurat, Rousseau and Others.*—Georges Seurat (1859-91), like Cézanne, found inspiration in the 16th- and 17th-century masters. At the same time modern scientific research into colour led him to develop a neo-impressionist technique, which has obscured his power of expressing structure and of welding form into balanced and monumental design. But he has exercised much influence, especially on the cubists, whose studio walls often carried reproductions of "Le Chahut," one of his last pictures.

Henri Rousseau (1844-1910), "le douanier," a very different figure, was once an octroi official in Paris (whence his nickname). He is the type of the primitive who tries to paint things as he knows them to be rather than as they appear. He used, for example, to measure his sitters with a footrule, and transfer these measurements to canvas. His work, which includes portraits, views of the suburbs of Paris, exotic landscapes based on recollections of military service in Mexico and figure compositions, is marked by emphasis on solidity, precision of handling, adjustment of the relative size of objects according to their importance as elements in design, and at times by a symbolic element.

In contrast to Rousseau is Gustave Moreau (1826-1898), a strange figure bred in the strictest academic tradition, who borrowed romantic fire from Delacroix and Chasseriau, and fed his imagination upon the myths of Greece and the East. He emerged from many years' retirement to become at the end of his life professor at the École des Beaux Arts, where his influence helped to breed a group of young painters with symbolist tendencies. As a teacher Moreau always encouraged self-expression based on close study of the old masters. In his own work Moreau stood for the use of painting to express the emotions, and built up a decorative art which sought to combine sombre rich colour with linear arabesque.

*Gauguin and Van Gogh.*—Paul Gauguin (1848-1903) was more definitely a *chef d'école* than any of the group now under consideration. After an impressionist phase, he became in Brittany the centre of the well-known Pont-Aven group, and there developed theories which were to govern all his later work. In 1891 he went to the Pacific Is., and, except for a brief return to France, spent the rest of his life there. Admiration of the primitive was at the base of Gauguin's art. Rejecting impressionism as a mere reproduction of nature not inspired by thought, he held that study of nature awakes emotions in the artist which he has to express by bringing into relation symbols, consisting of forms and colours. Though these colours and forms in his pictures might not actually exist in nature, he claimed them to be the pictorial equivalent of the grandeur, profundity and mystery of Tahiti. His latest work most completely embodies

these ideas in its use of boldly simplified contours, enclosing areas of rich purples, greens, reds and oranges. His art is primarily decorative and intellectual, revealing a less strenuous effort to express a third dimension than does Cézanne's. His symbolism, though not primarily literary, towards the end moved in that direction.

Akin to Gauguin in his outlook and use of colour is Vincent van Gogh (1853-90). Born in Holland, his early work shows the influence of the older Dutch masters and of the Hague School; association with the impressionists in Paris and with Gauguin at Arles led him to develop the use of heavy masses of vivid colour arranged in bold patterns, emphasised by black outlines and writhing arabesques of paint. A passionate lover of nature, and a mystic and idealist by temperament, Van Gogh believed that the artist's creative power was given to him to make men happy. Vehement personal passion is the note of his work. His colour ultimately became quite non-naturalistic, and was solely directed towards expressing his emotions in the face of nature; and his surface texture serves to increase the arresting, disquieting quality of his work. The third dimension did not play a dominant part in Van Gogh's work. His design, in which decorative simplification became increasingly marked, shows strongly the influence of Japanese art.

*Symbolism and Fauvism.*—The characteristic aims of the preceding group of painters—rejection of naturalistic representation, emphasis on solidity and structure, organised design, and the symbolic use of form and colour—appears in varying degrees in the work of their successors. The influence of Cézanne, which has modified or supplanted that of others, took some time to develop, and the first well-marked group appeared round Gauguin at Pont-Aven. Prominent therein was Paul Sérusier (b. 1864), who was one of the first to formulate a doctrine based on the ideas of Gauguin, Cézanne and Odilon Redon. He drew round him a group of *symbolistes* which included Maurice Denis (b. 1870), Pierre Bonnard, K-Xavier Roussel and Edouard Vuillard. This doctrine declares that a work of art must aim at the expression of an idea. Since it uses form for this purpose, it must be symbolic; and since the form as to be organised, it must be synthetic and decorative. The basis of the doctrine is a belief in correspondence between external forms and subjective states—not by association, but direct. Sérusier and Denis have given these ideas a mystical and religious application, largely under the influence of the *quattrocento* Italians.

In Bonnard (b. 1867) and Vuillard (b. 1867), however, the purely decorative element is uppermost, in a graceful and refined but over-precious treatment of material drawn from everyday life, influenced by Japanese art, and marked by elusive and delicate harmonies of green, blue, rose and yellow combined with grey. Closely akin to this *symboliste* group is another, whose best-known members were pupils of Gustave Moreau. The religious symbolic pictures of George Desvallières (b. 1861) are characterised by the use of arabesque and rich exotic colour; the more realistic art of Charles Guérin (b. 1874) by its decorative aim and search for tonal rather than for linear unity. The influence of Moreau, modified by the pupil's own temperament, is well seen in the fantastic, savagely distorted nudes and mysterious, sombre landscapes of Georges Roualt.

*Matisse.*—Far better known is his fellow-pupil Henri Matisse (b. 1869), who represents the expressionist side of symbolism. Academic and neo-impressionist phases never obscured a very personal use of line and colour whose decorative quality relates him to the Chinese and Japanese. A period of arbitrary distortions of the human figure, partly inspired by the study of negro art, marked a further stage in breaking away from representational art. These distortions, his apparently anarchic design and his decorative use of colour earned for Matisse the title of "Chef des Fauves," though he has not formed the centre of a well-marked group, despite his wide influence. It is difficult to acquit him sometimes of painting *pour épater le bourgeois*; but his latest work shows increased discipline and restraint, and is notable for the use of a sensitive contour enclosing delicate and harmonious colour.

Somewhat the same power is seen in the Italian painter and sculptor Amédée Modigliani (1884-1920), though his work is far more mannered than that of Matisse and lacks feeling for colour. Kees van Dongen (b. 1877 in Holland) mingles the influence of Matisse with that of Toulouse-Lautrec, and mainly shows the application of a *fauviste* recipe to the painting of fashionable Parisian society.

Different from the *symbolistes* and *fauves*, but equally in reaction against impressionism, are the painters who return to the outlook and methods of the *quattrocento* Italians. Among these are Jean Frélaut (b. 1879), notable for his sincere interpretations of the country and people round Morbihan in Brittany; and Félix Vallotton (1865-1926), whose angular, precise contours and definite colour pattern relate him to the primitives, and have won him the nickname of the "Cabanel of the Salon d'Automne." A definite Pre-Raphaelite tendency is represented in England by Joseph Southall, head of the Birmingham School of Art. Henry Lamb combines the influence of the Italian Primitives with that of Gauguin and Augustus John, in a dignified and sensitive art whose emphasis is largely on design. He has influenced among others Stanley and Gilbert Spencer, whose work is delicate and sincere, but tends to a conscious archaism. Eric Kennington, whose war paintings attracted much attention, has Pre-Raphaelite leanings, but is primarily academic in outlook.

*Cubism*.—To the manifestations of the modern movement so far considered, cubism is a marked contrast. It was a reaction not only against impressionism but against fauvism, and professed to stand for the introduction of order and discipline into painting. Some opponents of cubism, indeed, saw therein a return offensive of the academics. It owes its name and in part its origin to Matisse, from whose association with Picasso and others the movement took shape in 1908; and in conjunction with a similar group which included Albert Gleizes and Jean Metzinger, cubism won its first public recognition in the Salon d'Automne of 1913. To the influence of Cézanne and Seurat, which mainly inspired the movement, was joined that of negro and Polynesian art, in which there is a simplified treatment of the human form which emphasises its bulk and solidity, and a complete disregard of normal appearance in the effort to express an idea. Thus the cubists came to reject the reproduction of natural appearance. Nature, they hold, merely serves to awaken in the artist emotions which he expresses by a series of abstract forms, ordered and arrayed by his will. Thus cubism aims at creating a kind of visual music. In its most austere form it avoids curved lines and colour as pretty and sentimental; and even holds that a picture is not a decoration since that term implies dependence upon external objects.

From the first, great emphasis was laid on the expression of a third dimension. This aroused difficulties, which have separated the cubists into distinct groups. Expression of a third dimension introduced an element of resemblance to nature. Some painters accepted this so that their pictures are little more than arrangements of realistically painted cubes and cylinders; others rebelled against such a restricted art, and made of cubism merely an exercise in the expression of three-dimensional form. The purists, however, argued that art is not concerned with Euclidean space but with a special pictorial space, which we feel by our whole personality expanding or contracting before a picture; and that it is not the painter's business to create an illusion of a third dimension but to make live on a two-dimensional surface a reality of three dimensions. Further difficulties have been caused by development of a theory of simultaneity which justifies presenting on the same canvas several aspects of the same object. This often only comes to a mechanical arrangement of a number of separate impressions, whose disentanglement may be a source of interest, but makes cubism descriptive rather than pictorial.

*Picasso*.—Pablo Picasso (b. 1881 at Malaga) has been the dominating force in the movement, but by no means typifies it. With him cubism has been only a phase. To a realistic period, mainly influenced by Toulouse-Lautrec, succeeded a group of

reddish nudes, solidly constructed from simplified planes, which ushered in the cubist period. The earlier work in this showed some conformity to natural appearance, and was mainly in *grisaille*; later the forms became more abstract, the design more arbitrary and the colour more brilliant, sand and similar substances being embedded in the paint to give relief and variety of surface. Later came the influence of Ingres, especially in Picasso's drawings, some of which conform closely to natural appearance, with only enough distortion to give flow and rhythm. The chief characteristic of Picasso is his versatility. But it is doubtful whether he has achieved more than a series of exercises in different manners.

Other cubists have also reverted to representation. Georges Braque, whose long adherence to geometric forms, straight lines and sombre colour made him the purist of the movement, has executed admirable settings for the Russian ballet, and turns still life groups into flat patterns of attractive colour. Metzinger, one of the popularisers of cubism, paints artificial arrangements of natural forms, coarsely modelled with emphatic local colour; Auguste Herbin has become a heavy-handed landscape painter in the Cézanne tradition; Leopold Survage in his treatment of the figure has become almost academic. Of the leading figures in the movement, Juan Gris and Fernand Leger alone still exemplify its doctrines; and in general the influence of cubism may be said to have passed, save in giving a solid and mechanical quality to the work of those who once practised it.

Between the extremes of cubism and fauvism stands a considerable group of artists who derive something from both, but mainly witness the influence of Cézanne. Of these Albert Marquet (b. 1875) is primarily a painter of Paris and of the Seine, whose use of well-defined planes, with their tonal relations accurately expressed, is apt to degenerate into an ingenious system of notation. Jean Puy (b. 1876), in his landscapes of wide-stretching countrysides, has notable feeling for subtle variations in colour and tone. With Othon Friez (b. 1879) the organising instinct is uppermost, but he shows considerable power of retaining fresh and unspoiled his original conception. More consciously decorative than Cézanne, his mural paintings sometimes show the influence of Gauguin. Jean Marchand (b. 1883) and Dunoyer de Segonzac (b. 1884) are among those to whom cubism has been a gymnastic to develop understanding of form, but who rely on colour and tone to give solidity and a sense of space.

Marchand's early promise has scarcely been fulfilled, his recent work being empty and its colour forced. Segonzac has developed the use of the palette knife and thick impasto, working in a scheme of dark browns, greys and greens which are apt to be monotonous. His war paintings, which reflect a very personal emotion based on his own experience, are themselves the colour of Flanders mud. André Derain (b. 1880) is one of the most influential of younger painters; After a period influenced by Van Gogh and the neo-impressionists, he produced a series of truculent nudes and landscapes, which showed cubist and fauve influence in their simplified and distorted forms. His later work is more sober and naturalistic, though apt to be heavy and mannered. Mannerism also marks the dramatic landscapes of Maurice Vlaminck (b. 1876), with their heavy skies and contrast of sombre greens with vivid reds and pinks, Maurice Utrillo (b. 1883) mingles impressionist influence with that of Cézanne in his landscapes. Before the War, a limited palette, including black and white, and considerable attention to atmosphere and texture marked his work; replaced later by greater definition of forms and forcing of local colour. Marie Laurencin mingles the influence of Matisse and Renoir in her paintings of women and children, whose sprightliness does not conceal the lifeless formula on which they are based.

*Futurism*.—Modern art in most countries is an extension or adaptation of French ideas and methods. Spain has produced Picasso, but cubism is entirely Parisian in origin; and so much of the modern spirit as appears in Catalan painters such as Sunyer and Casals is derived from France. Futurism, however, is indigenous to Italy. The term has been loosely used, especially

*Picasso has been a major influence in recent painting. His Spanish heritage of irony and his dazzling French facility have sparkled now in blue, now in pink, with prismatic brilliance. This Harlequin from his "blue" period shows Picasso's mastery of linear composition and spatial relations before he undertook to show in one canvas all the facets of a subject conceived as a moving, variable idea.*

in England, to denote the modern movement as a whole; but strictly it applies to the doctrines of a group of Italian poets, sculptors and painters, first presented to the world in 1909 in a manifesto signed by F. T. Marinetti, the poet and high priest of the movement. These doctrines apply to art a general philosophy of life, based on the modern scientific theories which express all matter in terms of energy; and while denouncing all that the past has done (whence the name futurism) holds that movement and conflict are the dominant characteristics of modern life. Cubism, as dealing only with the static aspects of life, it rejects; impressionism it takes as a starting point, but claims to have surpassed.

The futurist's aim is to represent, not the appearance of objects at some particular point in their course, but the sensation of movement and growth itself. One method, which connects futurism with cubism, is to combine on one canvas not only what the artist sees, but what he knows and remembers about an object. Another, peculiar to futurism, is the use of "force lines." Every object, it is argued, is at a given moment the temporary outcome of continuously acting forces, whose character is indicated by the lines and planes enclosing it. Thus an object becomes simply the beginning or prolongation of rhythms conveyed to the artist by contemplation thereof; and these he represents in his picture by lines arranged to clash, harmonise or interplay in order to express states of mind such as chaotic excitement, happiness or interest. Colour the futurists use arbitrarily to assist in conveying these sensations.

Luigi Russolo is the most logical and orthodox of the futurists. The work of others, such as Carlo Carra, is little more than a catalogue of information about a number of different objects; though Umberto Boccioni, who has applied futurist theories also to sculpture, sometimes redeems his work by an interesting design. The gaily coloured, tapestry-like patterns of Gino Severini were among the more attractive futurist paintings; but his recent work under cubist and academic influences has become entirely commonplace. His career typifies the fate of futurism, which has found no new recruits, and has had but transient influence.

### III. NATIONAL TENDENCIES

*Great Britain.*—The British vorticists share some doctrines with the futurists; but the main forces shaping the modern movement in Great Britain are French. This movement first took shape in the studio of Walter Sickert, and resulted in the formation of the Camden Town group under the presidency of Spencer Frederick Gore (1878-1914), which developed into the more eclectic London group whose first president was Harold Gilman (1876-1919). At the same time Roger Fry (b. 1866), by his writings and by assisting to organise post-impressionist exhibitions in 1910 and 1912 at the Grafton Galleries, did much to make known the character of the modern movement in France, and to assimilate more closely thereto the English movement. Gore and Gilman represent the movement in its earlier stages. Gore's earlier impressionism was modified under the influence of Cézanne and Van Gogh by increased attention to structure and design, which for a time obscured his charming sense of colour. This reappeared in his latest work, done mainly at Richmond. Gilman emerged from a period influenced by Whistler and painters of the Vuillard type to one which gave increased emphasis to the third dimension and showed the influence of Van Gogh in the use of brilliant colour and the texture of paint.

Charles Ginner, whose work is akin to Gilman's, though without its vitality, describes their art as aiming at "the plastic interpretation of life through intimate research into nature." The emotions aroused by nature in the artist he must express by deliberate and objective transposition of nature on to canvas, so that he reveals the qualities in her which have moved him. The variety of line and colour in nature, joined to the artist's personality, will produce a decorative composition. This neo-realism (as Ginner calls it) is based on the attitude of Cézanne and Van Gogh towards nature; but gives an English turn to

that attitude by emphasising the part played by nature as compared with that of the artist. The French point of view is more evident in the work of the London group. Some of its members are still slaves to a French formula; others have based on French teaching a more individual art, notably W. B. Adeney, Roger Fry, Duncan Grant and Vanessa Bell. Grant's feeling for delicate and harmonious colour and for pattern gives his art characteristic quality, which over-absorption in problems of three dimensional form has at times obscured. C. W. R. Nevinson, having explored in turn impressionism, futurism and cubism, abandoned the geometric convention which marked his war paintings, to reveal an academic art masked by previous experiments.

Distinct in character is the vorticist movement, which had its origin in 1913 among certain members of the Camden Town group, and had as its leading figures the painters Percy Wyndham Lewis, Cuthbert Hamilton, Frederick Etchells, Edward Wadsworth and William Roberts, the poet Ezra Pound and the sculptor Henri Gaudier-Brzeska (1891-1915). Like futurism, it holds that modern art must be based on the character of modern industrial civilisation, whose features are complexity and dominance of the machine; and, since England is pre-eminently the type of the modern industrial country, this art will be an English art. But it rejects futurism as merely the cinematographic representation of a series of impressions; and joins the modern movement as a whole in claiming that the artist's work is not to copy nature, but to create new realities. Every phase of emotion has its appropriate means of expression in some particular form of some particular material, whose appeal is direct and not by association or allegory. These forms take shape and proceed out of the artist's "vortex" (hence the name of the movement), which is a general conception in his mind of relations in the universe through which ideas pass and take concrete shape, just as the general equation of a circle in analytical geometry becomes one particular circle when definite quantities are substituted for the algebraic symbol.

In 1920 the vorticists seceded from the London group to form the X group; but their first exhibition showed some modification in their practice. The earlier vorticist work was geometric and abstract, and owed much to cubism. Hamilton represents this phase; but others have turned towards expressing the structure of natural forms in the way exemplified by the work of Wyndham Lewis, while J. McKnight Kauffer has exploited geometric conventions with much success in posters. The interest of the earlier vorticist painting lies in disentangling in sequence the elements from which it is constructed; otherwise, though sometimes showing new and interesting combinations of shapes and colours, it presents only a barren world of geometrical forms.

*United States.*—In the United States, cubism, futurism and vorticism have all had their exponents among the younger painters, but have inspired no work of permanent interest or value. Modern French art has nevertheless materially modified the impressionism which had become a dominant force in American painting. Impressionist ideas had marked the work of the Society of National Artists, once representative of the advanced elements in American painting. On the dissolution of this body, many of its members joined the older National Academy, thereby establishing impressionism as one form of orthodoxy, exemplified in the landscapes of Twachtman and Robinson among the older men. Problems of light and atmosphere are likewise the main interest of Dewing, Childe Hassam and J. Alden Weir (d. 1920), and of the sea painters Carlsen, Dougherty and Waugh. The work of these men is primarily an echo of European ideas and the methods of an older generation.

More recently, however, various forces have tended to shape a distinctly American school. Among these is the rapid increase in the number of important art galleries throughout the country, which permits art students to study at first hand the old masters; the development of American art schools, with teachers of personality and originality, such as La Farge and Chase; and the consequent increase in the number of painters who remain in

America and find their material in characteristically American scenes. Such influences, combined with modern aesthetic theories, have resulted in more attention to problems of form and design, with greater breadth of treatment. Among figure and portrait painters, Robert Henri is notable for his versatility and vigorous, direct handling; John Sloan for his intensely realistic treatment of New York slum life; George Bellows (d. 1925) for his well designed and sympathetic interpretation of many phases of contemporary life, work and sport. Among landscapes the broadly decorative studies of suburban New York by Ernest Lawson and the vivacious rural and beach scenes of William J. Glackens may be mentioned.

Less concerned than any of these with problems of natural appearance was Albert Ryder (d. 1916), whose landscapes and figure studies are inspired by a highly romantic and very personal emotion, which links him to such painters as Delacroix. The mystical decorative compositions of Arthur B. Davies are conceived in the vein of a Fantin Latour, but are weak in design and drawing. In contrast is the strongly realistic approach of G. B. Luks, who produced several remarkable war paintings. Mural painters have also been active in America, the example set by Sargent in Boston being paralleled in public buildings at Pittsburgh, Baltimore, St. Paul, Minneapolis and elsewhere by the work of such painters (among others) as La Farge, Blashfield, and Alexander.

*Germany.*—In Germany the modern movement has been mainly inspired by that side of modern French art represented by Matisse and Derain. Cubism has not gained a firm footing there; though the Russian Jew, Marc Chagall, shows cubist influence in the sharply defined planes and angular design of his fantastic, vividly coloured decorations; and Lyonel Feiniger has adopted the cubist method of extension and development of planes. But arbitrary distortion and writhing arabesque have proved more congenial means of expression in an art which has always tended towards the romantic and symbolic. Native influences, such as Hans von Marées and the Munich decorative school, joined the study of El Greco and Matthias Grünewald in paving the way for an expressionist art in the full sense of the term—one which gives vent to every kind of emotion with unrestrained vehemence. A mystical temper and a mass of confused aspirations induced by the War have stimulated this development; but the movement was in being before the War, chiefly under the leadership of Wassily Kandinsky (b. 1866 at Moscow), a prominent member of a Munich group of painters, poets and musicians, whose aim was the expression through art of the "*innerer Klang*"—the soul of nature and humanity.

According to Kandinsky, colour and form have the power of producing spiritual vibrations quite apart from their ordinary meaning and associations; and a picture consists of an arrangement of form and colour whose spiritual values are in harmony with it and unite to express the artist's spiritual conceptions. Thus painting ceases to have representation as its purpose, and becomes analogous to music in its rhythmical arrangements of forms and colours. These may be borrowed from nature, but must have no external associations, and may be freely adapted and distorted to suit the artist's aim. Thus Kandinsky has points of contact both with the *symbolistes* and cubists; but he criticises the latter for reducing the construction of a picture to rules and formulas, and for paying overmuch attention merely to representing three-dimensional form.

Kandinsky's own work has become increasingly abstract in character, and consists of some early flat decorations, combining Russian and Munich influences; a group of more or less direct impressions of nature, inspired by Matisse; "improvisations" which represent spontaneous expressions of inner character; and "compositions" which, he claims, express a slowly formed and mature spiritual feeling. His most important disciple is Franz Marc (1880–1916), whose animal compositions, boldly designed in arbitrary colour, are his most typical work. The influence of Kandinsky has declined rapidly in recent years; and more relation to natural appearance is preserved in the work of the younger men. Prominent among these is Oskar

Kokoschka (b. 1886 in Austria), in whose early work appears the free distortion, sharp contrasts of light and shade, bold contours and thick impasto worked into arabesques, by which he conveys his excited and very personal vision. In his later work emphasis by these means is even more emphatic and merciless. The heads of his figures are balanced on tiny bodies, bizarre monsters are introduced, and the paint is literally thrown on to the canvas, with great channels made therein to mark the dominant lines of the design.

Painters of similar tendencies are Emil Nolde, Karl Hofer (whose work has affinities to that of Derain), and Karl Schmidt-Rottluff. The last, under the influence of negro sculpture, has become a coarser Matisse. The influence of an earlier generation of Frenchmen is seen in Max Pechstein (b. 1881), a founder of the "Brücke" expressionist group in Dresden, whose work owes much to Gauguin; and in Albert Werszgerber and Carl Caspar, both of whom base their design and use of colour on Cézanne. Max Slevogt (b. 1868) and Lovis Corinth (1858–1925) were among the leaders of the Berlin Secession, a split in the Berlin Kunstverein which marked the rise there of the modern movement. Both owe much to Matisse; Slevogt as a figure painter, Corinth in landscape. Associated with them in the Secession was Edward Munch (b. 1862 in Norway), who stands somewhat apart in his combination of realism and fantasy influenced by Manet, Toulouse-Lautrec and Seurat.

*Russia.*—In Russia the influence of French art has been no less marked than elsewhere, but has taken peculiar and characteristic shape. Towards the end of the 19th century Western, and in particular French, influence was represented by the realistic historical painters such as Ilya Repin and by a group of *plein-air* landscape painters. In reaction against their naturalism a decorative school developed, corresponding somewhat to the English Pre-Raphaelites, basing its work on old Russian art, and represented by Vassily Surikov (1848–1916) and Victor Vasnetsov.

Of this reaction the modern movement is really a development. One form it has taken is represented by Mikhail Vrubel (d. 1910), whose mystical symbolism recalls that of Gustave Moreau in its search to express things of the spirit in pictorial form; while Petroff-Wodkin is nearer to the French *fauves* in his simplified and distorted nudes and arbitrary use of colour. More important is a Petrograd group, consisting of historical painters whose aim is to reconstruct in decorative form a past epoch; not from living models dressed in costume of the period, but from the close study of every form of contemporary record. Thus the movement is primarily intellectual and literary, and has produced an art which, for all its refinement and delicacy, is inclined to be precious and a mere *réchauffé* of already used material.

Within the movement one group looks to the West. Alexander Benois has concentrated on the age of Louis XIV.; Konstantine Somov, the most individual of all, upon the period of 1830; and Eugène Lanceray upon the court of Elizabeth and Peter the Great. Stelletsky and Count Komatovsky, on the other hand, have gone to old Russia for their motives. Stelletsky is the purist of the group, his reconstructions of Russian mediaeval life being based on minute archaeological study of ikons, service books and similar sources. Nicolas Roerich has departed from strictly documentary methods in seeking to reconstruct primeval and prehistoric Russia in his fantastic flat decorations based on Russian legends, and thereby joins hands with the group represented by Vasnetsov. Rather apart is Boris Anrep (working now in England), who studied Byzantine art and the ikon, not in an archaeological spirit, but as exemplifying a means for the expression of human emotion. His work is principally in mosaic, submission to whose limitations, he holds, makes for the simplicity and directness which are often lost amid the technical possibilities of oil paint.

The close connection of modern Russian art with the theatre is another important characteristic, which has grown directly out of the decorative reaction against realism. Leon Bakst (d. 1925) represents one side of this. Originally associated with

*(The artist's aunt, daughter and mother)*

George Bellows set down fearlessly—and quite against the traditions—life as he saw it. His searching analysis and observation, and great originality in figure composition, give his work a vitality, a virility, that Americans like to call typically national.

the Petrograd historical group, he came into touch with Serge Diaghilev and became one of the chief designers of settings for the Russian Ballet. His use of line and colour relates him to the East; but, like Benois and Somov, his outlook and method are those of the West. Distinct in character is the art of Nathalie Gontcharova and M. Larionov. Using the methods of the Petrograd group, they took their material from Russian peasant art, as represented in the decoration of articles in daily use and in the "lubok," the Russian equivalent of the "images d'Épinal." This gives their earlier work notable simplicity and directness. French influence was not to be denied, however, and Gontcharova's setting for the 1914 production of the "Coq d'Or" and Larionov's "Les Contes Russes" of 1915 mark the invasion of the theatre by cubist ideas. The colour scheme was still that of Russian peasant art; but the design was based on abstract forms, and aimed at a rhythm in harmony with the music and the dances. To this development the name of *rayonnisme* has been given. Settings by French painters (notably Derain, Braque, and Picasso) have strengthened French influence.

*Other Countries.*—Though the modern outlook in painting has had influence in Scandinavia, America and Australia, it has not taken a form specially characteristic of local conditions or national temper. Painting in Australia is mainly a backwash from English impressionism; and the accomplished pen drawings of Norman Lindsay, which attracted much attention when exhibited in London in 1923, are little more than skilful pastiches on Rops and Beardsley. In Canada, on the other hand, has developed a distinct local school of landscape painting marked by decorative breadth of handling and feeling for the distinctive character of the country. Norwegian and Swedish painting is also mainly derivative, combining impressionist or expressionist ideas from France with flat decorative treatment in broad masses of colour inspired from Germany.

Much of the criticism levelled at the modern movement, like that once directed against impressionism, is merely a violent statement of personal preference. Weightier arguments point out that the emphasis given in the modern movement to the third dimension merely exalts one element in natural appearance, and urge that since the painter works on a flat surface design must ultimately be based on the play of contour. Also, it is said, modern methods of simplification and distortion tend to become formulas which prevent sincere and spontaneous expression no less than older conventions. But contention chiefly centres round the question of representation. It is argued that a purely abstract art, which takes no account of the ideas and emotions conveyed by the objects represented, is a limited and empty affair. Rhythm in the plastic arts, no less than in literature, must emphasise some meaning; and form takes on a significance by association, if not with specific objects, yet with general ideas of mass, space and movement. Recent work has to some extent justified and admitted these criticisms, partly by the greater tendency to flat patterning as compared with expression of volume, partly by the increasing weight given to representations of natural appearance.

(W. G. C.\*)

**PALAEOBOTANY** (see 20, 524).—Palaeobotany, or the science of the study of fossil plants has three main aspects, dependent on the nature of the remains available for study.

(1) External impressions and casts of plants, such as fern leaves found in shale beds, for instance, which are given specific names and often are of value in connection with stratigraphy and the sequence of the extinct floras of various geological epochs.

The identification and correlation of these fragments is essentially an international work, and depends on a wide knowledge of the type specimens in all countries.

(2) Petrifications of the inner detail and cellular anatomy of fossil plants, such as stems, seeds, etc., found principally preserved in silicified or calcified mineral balls or nodules, primarily of botanical interest in revealing the structure and life histories of extinct types. The originators of the meticulous kind of investigation they require were principally the French, English and German palaeobotanists of last century, though now petrified remains are being discovered and investigated in many countries.

(3) The peculiarly preserved "mummified" masses of plant material known as coal of whatever geological age, the exact nature and detailed structure of which has long been the subject of speculation. In spite of its huge commercial importance, it has received but scant investigation on truly scientific lines. Collaboration between palaeobotanists and chemists as well as geologists, is yielding a mass of new data, principally about British and American coals (see COAL).

*Relations with Anatomical Botany.*—Progress in palaeobotany essentially goes hand in hand with that in anatomical botany, each stimulating and filling in the gaps in the other, and it is more and more becoming impossible to discuss the anatomy or the phylogeny of the great groups of living plants without reference to their fossil ancestors.

*Angiosperms.*—The Angiosperms, the greatest of all living groups, have principally yielded plant "impressions" rather than anatomical material. These are common in a number of Tertiary and Upper Cretaceous horizons; and voluminous memoirs have been published on them in recent years, principally by E. W. Berry of America. The Dakota sandstones have yielded perhaps the handsomest series of large angiospermic leaf impressions in the world. From the United States also emanated substantial work on the angiospermic leaf impressions of the West Indies by Hollick (1924). A memoir from China, published at Peking (1922), is R. Florin's account of the plant impressions of early Tertiary age of Manchuria. Upper Cretaceous Angiosperms were described by Stopes and Fujii from Japan, among which is the earliest known petrified flower. This is of monocotyledonous type.

*Tertiary Material.*—In England, the rich deposits of Tertiary material, so long neglected, have been partly investigated by the newer methods which yield microscopic data about the cuticles, by H. Bandulka (1923-4). Similarly R. Kräusel had investigated Tertiary impressions, discovering many interesting microscopic fungi upon the remains. The Arctic floras were revised (1925) in a jubilee memoir by Seward. Whether the Monocotyledons or the Dicotyledons are the more primitive is not settled by the fossil record. With the exception of palms, fossil Monocotyledons are very few. Many discussions have raged about the evidence afforded by the angiospermic fossil floras on ancient climates, particularly centring around Dr. Knowlton of America. A greater regional diversity, and less world-wide similarity of climate over long epochs than was formerly assumed, may be taken to be the main result of closer investigation (see CLIMATE).

The origin and phylogenetic source of the Angiosperms is still a mystery. Authenticated leaf impressions do not go very far back, and petrified Angiosperms are exceedingly scarce in the earlier Cretaceous deposits, and unknown before that. In spite of various identifications, no reliable material of modern angiospermic type has been found as early as the Wealden in Britain or approximately the Neocomian in any part of the world. Impressions claimed to be such have proved to be portions of fern leaves with reticulate venation, such as *Dictyophyllum* (Berry and Stopes).

The earliest authentic Angiosperms in the world are from the Lower Greensand or Aptian, of England. This flora is of a rich mixed type, is markedly distinct in other ways, and contains the famous *Bennettites Gibsonianus* of Carruthers, and many conifers as well as ferns. The Angiosperms, discovered by

Stopes, are well petrified portions of secondary woods, and are of 5 genera, named *Cantia*, *Woburnia*, *Sabulia*, *Aptiana* and *Hylthia*. They are unlike each other anatomically, one having enormous wood vessels, and another very minute, nor do they show any "primitive" or pseudo-angiospermic features. They have the characteristics of highly organised angiospermic secondary timbers.

The origin of the Angiosperms clearly lies in an earlier geological epoch. Jeffrey and his American school have enunciated the view that the soft small herbaceous plants now living are less primitive than the woody trees. The matter still awaits further data from actual species of an early geological age. Interest in such theoretical discussions has been greatly enhanced by the discovery and description by H. H. Thomas of his Jurassic genus *Caytonia*.

*Gymnosperms*.—Gymnosperms, of tree-like build, date back to very early palaeozoic times, and are represented by a rich variety of material, including external casts, "mummified" cuticles and well-petrified woods. A steady stream of memoirs dealing with the comparative anatomy of fossil and living Gymnosperms has been maintained.

Petrified remains of numerous genera of the modern Coniferae are found throughout the Tertiary and Mesozoic horizons. Whether the Abietineae or Araucarineae are the older stock is much discussed. The latest edition of Scott's classic textbook (1923) leaves the subject still open. The ancient gymnospermic types of the Cordaiteae were most abundant and varied in the Carboniferous epoch, but persisted into the Permian and were already well established in the Upper Devonian. Anatomically preserved stems and leaves yield some of the most beautifully petrified and satisfactory material for microscopic study. Notable early representatives of this group were found at the very base of the Carboniferous of Kentucky and described by Scott and Jeffrey. Various species form series of almost connecting links between this Palaeozoic group and the typical pteridospermic types. Very full descriptions of those interesting seed plants are to be found in Scott's "Studies."

Returning to the higher group, the Bennettitales, we have to deal with another entirely extinct, but pre-eminently Mesozoic family. A few stragglers died out in the early Tertiary, but the rich growths preserved in such perfection and abundance which proved the basis of the discoveries of Carruthers, Wieland, Lignier and Stopes, all date from the Mesozoic. Wieland's two magnificent volumes (1916) contain restorations of these unique plants which have served as the theme of countless discussions. The fructifications, preserved both as surface casts and as petrified cones, even containing the tissues of the embryos, consisted of seed-bearing cones surrounded by perianth-like bracts. The mass of seeds contained in some of those must have been enormous, e.g., *B. abbianus*, Stopes, from the English Gault, had not less than several thousand seeds in one cone.

Though the external appearance and vegetative anatomy of the group were generally like those of the living cycads, the fructification irresistibly recalls that of the Angiosperms, and many authors have compared them and concluded that the Bennettitales point out the line of descent of the Angiosperms. This view does not generally commend itself. The other great Mesozoic group, the *Williamsoniaceae*, chiefly known through Nathorst's work on Swedish forms, and more recently by Thomas's beautiful species from the English Jurassic, seems to be a more popular candidate for the honour of fathering the Angiosperms. The series linked up by *Williamsoniella*, *Caytonia* and *Grithorpha* is one of the most beautiful results of recent palaeobotanical work; but their angiospermic affinity is more critically treated on the Continent than in England, particularly by Gothan in Germany. The abundance of the Bennettitales in Europe and America makes the dearth of the group in Asia conspicuous, and interest thus attaches to the brief account of a trunk from Hokkaido, Japan, by A. Kryshlovich.

*Cycadales*.—The modern Cycadales, though primitive among living plants, are unimportant in the fossil record, which contains but little evidence of their history.

*Pteridosperms*.—The Pteridosperms, a wholly extinct group, bulk largely both in actual number of specimens and in the interest and importance of their structure in the Carboniferous epoch. To impressions of their foliage, long considered true ferns, numerous generic names have been given, such as *Sphenopteris*, *Alethopteris*, etc. The stems and seeds investigated principally by Williamson, Scott, Oliver and Kidston were, just before 1910, all linked in association with each other to form the phylogenetically pregnant group of the "seed ferns" or Pteridosperms. Much detail has since been added, which is well summarised in Scott's "Studies."

*Pteridophytes*.—The Pteridophytes, or ferns proper, are extensively represented in all types of preservation in all geological epochs. Considerable detail has been added to the existing knowledge of the group since 1915. Anatomical data have been chiefly acquired about Carboniferous species. Of families with living representatives the most important extensions of knowledge have been made in the Osmundaceae in which family Kidston and Gwynne-Vaughan (1914) have been the most notable in filling in anatomical series for a wide range of geological time.

*The Marattiaceae*.—These are represented in the Coal Measures and Permian by the large and well preserved genus *Psaronius*, has long been well known, but knowledge was usefully clarified and increased by P. Bertrand in his paper on the anatomy of ancient ferns and Count Solms-Laubach on *Psaronius* (both in 1911) followed by Pelourde in 1912.

Tempskya, an extinct type of peculiar anatomical structure and wide geological distribution, was at last made clear by the work of Kidston and Gwynne-Vaughan. Access to their original paper, published in Russia, is difficult and reference should be made to Stopes (1915) and Seward (1924). The extinct family of the Botryopterideae, the most extensive Carboniferous family, is represented by many genera known from exceptionally detailed studies of excellent petrifications, particularly by Bertrand, Scott, Kidston and Gordon. The sporangia and cuticle structures of many species of ferns have also been studied by the modern methods of treating mummified remains, and results from the Palaeozoic and Mesozoic supplement and give significance to the work of Bower on recent ferns.

*Lower Pteridophyta*.—Of the *Lycopodiaceae* almost the whole of our present anatomical knowledge was accumulated before 1910. The same applies to the *Calamariaceae*, with the exception of Thomas's paper on the leaves in 1911 and the elaborate memoir on the Calamites of Western Europe by Kidston and Jongmans. In the more primitive groups, active interest was shown by Halle in the Devonian flora from Norway. He described the external morphology and some structural details of a number of species which have proved of the greatest morphological significance. Kidston and Lang followed with details of the Devonian flora contained in the now famous Rhynia cherts.

*Psilophyton*.—This has now become of peculiar interest since Rhynia has been discovered in plentiful anatomical material. This and other Devonian genera have been described by Kidston and Lang in several large memoirs, and a new class, the Psilophytales, has been instituted to include *Psilophyton*, *Rhynia* and some minor genera. The essential and most interesting morphological feature is that the simple branching plants bore sporangia at the ends of certain branches without any relation to leaves or leaf-like organs. *Sporangites* of Halle, *Psilophyton* of Dawson, and the new genera of Kidston and Lang represent the earliest known land flora, and though the genera differ in details they all show a remarkable simplicity of structure, with terminal sporangia. Their anatomy and morphology are still under discussion, and are of deep phylogenetic and morphological significance. The view put forward by Kidston and Lang, contrary to that held by most morphologists, is that this ancient family supports the idea that the sporangium of the Pteridophyta is not an organ *sui generis*. The *Characeae*, an old family still persisting, has received careful handling by J. Groves, with the discovery of many beautiful new fossil forms.

The Bryophytes are still almost unknown as fossils, but two papers on some fossil mosses have recently been published, one

by Walton and another by Weyland (1925). Certain bryophytic features in the genus *Hornea* from the Devonian have led to discussion of the morphology and phylogeny of the groups, but the gaps in the fossil records of mosses are so all embracing that one can only await the discovery of material.

**Algae and Fungi.**—Algae and fungi are special palaeobotanical problems, and the chief recent worker in this field is J. Pia who has published a number of smaller and one very large memoir on the Siphonae (1920) but apparently in complete ignorance of the volume on the same subject published by the British Museum. Incidental to other genera, microscopic fungi are now frequently described, particularly in petrified woods. Memoirs on the stratigraphic aspects of fossil plants, describing fossil floras from various localities and horizons, have been numerous, notable cases being the last paper published by the great Nathorst, on the Culm flora of Spitsbergen (1920), a continuation of his famous studies of the fossil floras of the Arctic, and the magnificent memoirs by R. Kidston, on which he was engaged at the time of his death, of which four parts had been published by the Geol. Survey, with numerous plates. Kidston's unrivalled work on the British Coal Measure plants reveals the richness of our native fossil flora, and links up all branches of palaeobotanical work in complete surveys of Carboniferous genera. Some small memoirs on the German Culm come from the pen of Robert Potonié junior, the son of the famous Berlin professor. From the antipodes Dr. Walkom's series of memoirs on the fossil impressions and petrified plant remains of Queensland throw welcome light on an area of which far too little is known. The historically interesting Indian Gondwana flora is revised in a handsome memoir by Seward and Sahni (1920) and Yabe added to our very scanty knowledge of oriental fossil plants in the memoirs published by the Imperial University (1921-2). As general resumés of what has been accomplished, A. Carpentier's *Revue* of palaeobotanical works is invaluable, and we must regret that the two most recent volumes (1923) carry the subject no further than 1919.

**Coal.**—Among the most comprehensive works of the old school is the exhaustive memoir, *Interrelations of the Fossil Fuels*, by Stevenson (1916). An immense amount of more detailed work has been accomplished. Many of the earlier workers (Dawson, Williamson, Huxley and others) had been interested in the spores and small débris of plants to be seen in sections of some coals, and in recent years Lomax had done much to popularise in botanical and geological circles, transparent thin sections of coal showing preserved plant remains. Stimulated by the importance fuels assumed in the War, more exact correlations and investigations into coal structure were attempted. Stopes and Wheeler's *Memoir on the Constitution of Coal* (1918) was shortly followed by Stopes's paper on the "Four Visible Constituents in Banded Bituminous Coal" (1919) in which the four ingredients *Fusain*, *Durain*, *Clarain* and *Vitrain* were detected and diagnosed. These terms have passed into the universal nomenclature (see COAL). The chemical, coking and other properties of the constituents have been studied in further detail by Wheeler, Lessing, Sinnott, Tideswell and others. Somewhat similar work is also being carried on in Japan by Iwasaki (see *A Fundamental Study of Japanese Coal*, 1920-2) and in the United States by Jeffrey, White and Thiessen. The latter's work introduces the name "anthraxylon" to represent "woody tissue" and applies it at times where woody tissue is not proved to have existed, and treats it as though it were the equivalent of "vitrain" which it is not. In spite of this, however, rapid advance in our knowledge of the marvellous masses of mummified plants is being made.

The mass of coal is no longer looked on as a unit, but the attempt is being made to separate out its component parts and to arrive at the chemical and palaeontological structure of minute zones of coal, which contain portions differing both in their anatomical, physical and chemical natures, the ash content, coking qualities and other correlated features.

**BIBLIOGRAPHY.**—The bibliographies in the following books will give most of the references, except monographs published recently:—

E. W. Berry, *Lower Cretaceous Deposits of Maryland* (1913), and *Upper Cretaceous and Eocene Floras of South Carolina and Georgia* (Washington, 1914), and many other quarto memoirs published by U.S. Geol. Surv.; J. M. Coulter and C. J. Chamberlain, *Morphology of Gymnosperms* (Chicago, 1910); E. C. Jeffrey, *The Anatomy of Woody Plants* (Chicago, 1917); D. H. Scott, *Studies in Fossil Botany*, ed. 3 (London, 1920-3); A. C. Seward, *Fossil Plants*, vol. 1 to 4 (Cambridge, 1917); M. C. Stopes, *Catalogue of Cretaceous Plants in the British Museum*, vol. 2 (London, 1915); M. C. Stopes and R. V. Wheeler, *The Constitution of Coal* (London, 1918); R. E. Torrey, *The Comparative Anatomy and Phylogeny of the Coniferales*, pt. 3 (Boston, 1923); G. R. Wieland, *American Fossil Cycads*, vol. 2 (Washington, 1916). (M. C. S.)

**PALAEOONTOLOGY** (see 20.579).—During the period 1910-26 the science of extinct forms of life made remarkable progress, especially in North America, where explorations and studies were less interrupted by the World War. The contact of palaeontology with other sciences—even those apparently remote like astronomy, physics and chemistry, less remote like comparative anatomy, or very intimate like geology—was one of the outstanding features of the synthetic work accomplished. Of transcendent interest, however, was the contact between mammalian palaeontology and anthropology, especially through the researches of William K. Gregory of the American Museum of Natural History and of G. Elliot Smith of London University.

**Principal Synthetic Works.**—Chief among the synthetic works in pure palaeontology are those of the Austrian palaeontologist Othenio Abel, *Grundzüge der Paläobiologie der Wirbeltiere* (1912), *Die Stämme der Wirbeltiere* (1919), and *Lehrbuch der Paläozoologie* (1920), which give masterly reviews of the whole fossil history of the vertebrates, especially in analogous and convergent adaptation. In invertebrate palaeontology the reader is referred to Amadeus Grabau's *Principles of Stratigraphy* (1913) and *Textbook of Geology* (1920-1), in which are summed up the principles derived from the teachings of Waagen and Neumayr in Germany, of Hyatt and Beecher in America, in pure palaeontology and in application to geology. A broad synthetic treatment of climate and time in relation to the evolution of life is that of the late Joseph Barrell (1917) in his *Rhythms and the Measurements of Geologic Time*. The best synthetic treatment of climate, time and geologic change in relation to the geologic origin and the migration of the different vertebrate groups is William Diller Matthew's *Climate and Evolution* (1915). The subdivisions of geologic time and the successions of faunas and climates are broadly reviewed in the *Textbook of Geology* by Louis V. Pirsson and Charles Schuchert (1915; rev. ed., vol. 1, 1921). The latest summary of the geology, past physiography and palaeontology of the world is found in the French edition of the great work of Eduard Suess, *Das Antlitz der Erde*, translated and annotated by Emmanuel de Margerie as *La Face de la Terre* (1902, 1918). The comparative evolution of the mammalia of the eastern hemisphere and of North America is broadly treated in Henry Fairfield Osborn's *Age of Mammals* (1910); while the mammals of North and South America are compared in W. B. Scott's *History of Land Mammals in the Western Hemisphere* (1913). A broad treatment of the whole subject of invertebrate and vertebrate evolution is given in Richard S. Lull's *Organic Evolution* (1917) and a synthetic review of the earth's history, from its solar beginnings to the Age of Man, in Osborn's *Origin and Evolution of Life*.

**Life Epochs of Geologic Time.**—The time scale in the accompanying table is taken from the work of Pirsson and Schuchert of 1915, modified by the substitution of geologic time units for years. There is a growing indisposition to reckon past time in terms of years, and a growing tendency to substitute a relative term like *time units*, because of the enormously wide discrepancy between the older estimates of geologists, based on sedimentation and the thickness of the various assemblages of rocks which taken together make up the whole geologic time scale, and the estimates of physicists, based on the slow liberation of radium from radioactive minerals. The radium estimates of the age of the earth range as high as 1,400,000,000 years for the oldest known rocks, according to Barrell, who has adopted the calculations of Rutherford and others based on the "rate of disintegration" of radioactive minerals (see PHYSICS). For the contrast see the table on p. 14.

The most original part of Barrell's contribution was the measurement of time from the base of the Palaeozoic to Recent time by new palaeophysiographic methods, taking into account particularly the rhythms or cycles of dry and moist climates and of elevations and depressions, theories which were originally interpreted by T. C. Chamberlin and popularly treated by Ellsworth Huntington, the physiographer of Yale University.

| Life Epochs                                                         | Walcott (1893) Years       | Barrell (1917) Years    |
|---------------------------------------------------------------------|----------------------------|-------------------------|
| Age of Man and of Mammals—Cenozoic                                  | 3,000,000                  | 55,000,000—65,000,000   |
| Age of Reptiles—Mesozoic                                            | 9,000,000                  | 140,000,000—180,000,000 |
| Age of Amphibians, Fishes, Invertebrates—Palaeozoic                 | 18,000,000                 | 360,000,000—540,000,000 |
| Precambrian Time—Evolution of Invertebrates and of Unicellular Life | 30,000,000                 | 600,000,000—800,000,000 |
| Minimum Total                                                       | 90,000,000 (Geikie, 1899)  | 1,200,000,000           |
| Maximum Total                                                       | 400,000,000 (Geikie, 1899) | 1,400,000,000           |

A few decades ago the physicists and mathematicians, especially Kelvin and Tait, insisted that the earth could not be more than 10,000,000 to 20,000,000 years old; now the physicists are extending the age of the life period to 1,400 million years, as estimated by Barrell (1917). The most recent determination by physicists, as reviewed by Lord Rayleigh (1921), takes into consideration the 'transmutation' of chemical elements; for example, in the bröggerite of the Precambrian rocks at Moss, Norway:—

Taking the lead as all produced by uranium at the rate above given, we get an age of 925,000,000 years. Some minerals from other archæan rocks in Norway give a rather longer age. The helium method is applicable in some cases to materials found in the younger formations, and proves that the ages even of these are to be reckoned in millions of years. Thus the helium in an Eocene iron ore indicated 30,000,000 years at least. The upshot is that radioactive methods of research indicate a moderate multiple of 1,000 million years as the duration of the earth's crust as suitable for the habitation of living beings, and that no other considerations from the side of pure physics or astronomy afford any definite presumption against this estimate.

Applying this estimate to the evolution of a familiar mammal like the horse it might be said that the four-toed horse (*Eohippus*) existed 30,000,000 years ago, a somewhat larger estimate of the life period of the horse than that demanded by palæontologists. In the same discussion W. J. Sollas comments on the expansion of time estimates proposed by physicists:—

The age of the earth was thus increased from a mere score of millions to a thousand millions and more, and the geologist who had before been bankrupt in time now found himself suddenly transformed into a capitalist with more millions in the bank than he knew how to dispose of (see GEOLOGY).

In this connection we may recall the fact that as early as 1859 Charles Darwin pointed out that the high degree of evolution and specialisation seen in the invertebrate fossils at the base of the Palaeozoic, namely, the Cambrian, proved that Precambrian evolution occupied a period as long as, or even longer than, that of Cambrian to Recent time (see Table I.). Poulton, the leading disciple of Darwin in England (1896), declared that 400,000,000 years was none too long for the whole life evolution period; this would allow 200,000,000 years for Precambrian time and another 200,000,000 years from Cambrian to Recent time.

*Walcott's Revelation of Precambrian and Cambrian Life.*—Charles D. Walcott (1899, 1914) has discovered the remains of life in the Precambrian (Proterozoic) rocks of North America and has been able to give us a fragmentary picture of the fauna and flora of that very ancient period. In Montana, at a depth of nearly 10,000 ft. below the earliest Palaeozoic rocks (Cambrian), he found evidence of ancient reef deposits of calcareous algae, which ranged upward through 2,000 ft. of strata. Above these reefs are 3,000 ft. of shales containing worm trails and the fragmentary remains of large crustacean-like organisms. From rocks of approximately the same age in Ontario, Canada, he has described sponge-like forms (*Alcockania*) which are of such generalised structure that it is difficult to decide whether they should be regarded as sponges or as archaic corals. These few plant and animal remains are all that are known from remotely metamorphosed rocks of Precambrian time, but the existence of annelids and possible arthropods marks a break into the hitherto unknown Precambrian. Walcott's most surprising discovery in Precambrian time is a monad or bacterium attributed to *Micrococcus* sp. indet. from the Algonkian of Montana, but probably related to the existing *Nitrosomonas*, one of the prototrophic bacteria, which derives its nitrogen from ammonium salts.

In 1910 Walcott discovered in the Cambrian (Burgess) shales of Alberta, Canada, a marvellously rich fauna whose preserva-

tion is so perfect that the setae of the worms, the jointed appendages of the trilobites, the impressions of soft-bodied medusae and holothurians, and even the alimentary tract and stomach of certain of the crustaceans can be seen on the shale surfaces almost as clearly as in living forms (Plate I.). This discovery fairly revolutionises our knowledge of the anatomy of the delicately organised as well as the chitinous-armoured forms, like the trilobites. Including the new forms contained within these Albertan shales, the Cambrian marine fauna is now known to be far more abundant than even imagined by Darwin, comprising some 1,500 species; 1,200 of which occur in North America. From Lower as well as Middle Cambrian (Burgess) faunas, it appears that the Precambrian invertebrates had probably become completely adapted to all the life zones of the continental and oceanic waters, excepting possibly the abyssal. All the principal phyla—the jointed arthropoda (including the trilobites among the crustaceans and the merostomes among the arachnids), segmented worms (Annelida), echinoderms, molluscs (including pelecypods, gastropods and primitive cephalopods), brachiopods, medusae and other coelenterates and sponges—were presumably established in Precambrian times.

The Cambrian fauna has been made known to us in large measure through the field discoveries and monographic studies of Philip Lake (1906) for Great Britain, of Walcott (1909–21) for North America and of Cowper Reed (1915) for India. The great variety and high specialisation of the Cambrian marine forms, including representatives of all the known marine invertebrate phyla, is in harmony with the trend of discovery among the vertebrates; which is to put the origin of existing families very far back into the Age of Mammals and even into the Age of Reptiles (Mesozoic). In fact, the antiquity and persistence of modern types, as distinguished from modern genera and species, is an illustration of a very far-reaching principle, namely, that the most stable form of energy in matter known is that of the hereditary chromatin on which this extraordinary preservation of the main features of the ancestral type depends. Next to the stability of the properties of the chemical elements, which pass into each other by transmutation, the most stable physicochemical properties are those which form the hereditary basis of life.

*Freshwater and Terrestrial Origins.*—The eurypterids appear as contemporaries of the Cambrian trilobites and traces of them are found in Precambrian rocks; they attain to their acme in Silurian time and develop into the eight-foot giants of the fauna of the Devonian of Scotland and eastern North America, suffering extinction at the close of the Palaeozoic. In 1916 appeared Marjorie O'Connell's memoir, entitled *The Habitat of the Eurypterida*, giving as the summation of her studies that throughout their entire phylogenetic history the eurypterids lived in the rivers; a conclusion accepted in the main by Schuchert (1916), with the modification that they also appeared to have lived at times in the brackish waters of more or less large bays and possibly in limited numbers even in the seas. Many other origins formerly traced to the sea have more recently been traced to fresh water.

In 1900 T. C. Chamberlin put forward the hypothesis of a prevailing freshwater origin both for the ancestral backboneed animals known as chordates as well as for the much more ancient arthropods, the eurypterids. His strong influence was needed to overcome the widespread notion that all forms of life originated in the sea; and, one after another, theories of freshwater and terrestrial origin have replaced the theory of marine origin. Early in 1916 Barrell pointed out the influence of Silurian-Devonian climates on the rise of air-breathing vertebrates and freshwater origin in Devonian time under seasonal rainfall.

TABLE I. *Life Epochs and Geologic Time Units of Europe and North America (After Pirsson and Schuchert, 1915; issued by Osborn in 1918).*

| MILLIONS OF TIME UNITS | ROCKS CHIEFLY UNMETAMORPHOSED: SEDIMENTARY PREDOMINANT; IGNEOUS SECONDARY. ENTOMBED FOSSILS DIRECT EVIDENCE OF FORMER LIFE. | TIME UNITS | AGE OF MAN                    | AGE OF MAMMALS | CENOZOIC              | QUATERNARY                          |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------|------------|-------------------------------|----------------|-----------------------|-------------------------------------|
|                        |                                                                                                                             |            |                               |                |                       |                                     |
| 5                      |                                                                                                                             | 9,000,000  | AGE OF REPTILES               |                | MESOZOIC              | UPPER CRETACEOUS                    |
|                        |                                                                                                                             |            |                               |                |                       | LOWER CRETACEOUS (COMANCHEAN)       |
| 10                     |                                                                                                                             |            |                               |                |                       | JURASSIC                            |
|                        |                                                                                                                             |            |                               |                |                       | TRIASSIC                            |
| 15                     |                                                                                                                             | 18,000,000 | AGE OF AMPHIBIANS             |                | PALAEOZOIC            | PERMIAN                             |

Schuchert continues that the probable freshwater life of the eurypterids opens a vista into continental life as far back as the Upper Cambrian. Other merostomes related to the eurypterids radiated out from the fluviatile faunas of Cambrian, Ordovician and Silurian time, while in the Devonian rivers dwelt great spider-like eurypterids together with forms so similar to scorpions that they might be called river scorpions, and others that were active swimmers. O'Connell's argument regarding the freshwater eurypterids applies equally to *Limulus*, the horse-shoe crab. In brief, the existence of freshwater faunas no less varied than the marine faunas is beginning to be traced back to Lower Cambrian time. O'Connell shows that the entire phylogeny of the eurypterids, which includes about 160 species from the Precambrian to the end of the Palaeozoic, distributed in 78 geologic horizons throughout the world, points to migrations like those of fishes from the headwaters of interlacing river systems and, taken with other evidence, strongly supports the theory of Predevonian river life as opposed to the general assumption of marine life of all early faunas.

It now appears that beginning in Precambrian time the trilobites, by wide adaptive radiation, reached the acme of their development in the Cambrian, displaying a high degree of articulation and specialisation of appendages, suffered a marked decline after the Silurian, and became extinct at the end of the Palaeozoic. James Perrin Smith, who has made a very exhaustive analysis of cephalopod evolution and, especially of the Triassic ammonites, observes that the evolution of form continues uninterruptedly even where there is no evidence whatever of environmental change.

*Principal Literature, Cambrian to Pleistocene.*—A few of the major contributions to our knowledge of the life of the Palaeozoic are: *Cambrian Geology and Palaeontology* (1910) and *Cambrian Brachiopoda* (1912) by Charles D. Walcott; *Cambrian Fossils of Spiti* (1915) and other papers on the Palaeozoic of India by Cowper Reed; *A Monograph of British Cambrian Trilobites* (1906) by Philip Lake, and *A Monograph of British Graptolites* (1901) by Gertrude Elles and Ethel Wood. The foraminifera have been treated by E. Schellwien, *Monographie der Fusulinen* (1908-12); the bryozoa by R. S. Bassler, *Early Palaeozoic Bryozoa of the Baltic Provinces* (1911) and G. W. Lee, *British Carboniferous Trepostomata* (1912); the echinoderms by R. T. Jackson in his memoir on the *Phylogeny of the Echini with a Revision of Palaeozoic Species* (1912), and by Frank Springer in his monograph *Crinoidea Flexibilia* (1920) and in numerous shorter contributions. The ancient arthropods, including, besides the trilobites, merostomes and other arachnids and also insects, have been described by J. M. Clarke and R. Ruedemann in their memoir on *The Eurypterida of New York* (1912), by Alexander Petrunkevitch, *A Monograph of the Terrestrial Palaeozoic Arachnida of North America* (1913), by R. I. Pocock, *A Monograph of the Terrestrial Carboniferous Arachnida of Great Britain* (1911), and by F. Meunier, *Nouvelles recherches sur quelques insectes du terrain houiller de Commeny (Allier)* (1906-12). The literature on the Mesozoic contains more references to ammonites than to other groups, because of their abundance and palaeontological importance. The ammonite faunas of the Triassic have been described by J. Perrin Smith, *The Middle Triassic Marine Invertebrate Faunas of North America* (1914), and by Carl Diener, *The Trias of the Himalayas* (1912), *Japanische Triasfauna* (1915), and other papers on the Triassic of the Himalayas and southern Europe (1915).

For the Jurassic there are the classic volumes by S. S. Buckman, *Yorkshire Type Ammonites* (1909-19) continued in the *Type Ammonites* (1920) and the memoir by C. Burckhardt, *Faunes Jurassiques et Crétaciques de San Pedro del Gallo* (1912) for Mexico. The studies on Cretaceous ammonites have been more local in character and include: E. Stolley's *Beiträge zur Kenntniss der Cephalopoden der norddeutschen Unteren Kreide* (1911-2), D. N. Sokolov's *Zur Ammoniten Fauna des Petschoraschen Jura* (Russian) (1912), H. Yabe and S. Shimizu's *Notes on Some Cretaceous Ammonites from Japan and California* (1921), and numerous papers by A. de Grossouvre, W. Kilian and E. Haug for France and the Mediterranean region. The silicious sponges which are so well represented in the Mesozoic have received the most careful microscopic study by the students and followers of Zittel. Pioneer work was done in England by the late George Jennings. Hinde, *A Monograph of the British Fossil Sponges* (1887-1912), and this work was followed in Germany by A. Schrammen's *Kiesel-spongien der Oberen Kreide von Nordwestdeutschland* (1910) and R. Kolb's *Die Kiesel-spongien des schwäbischen Weissen Jura* (1911). Special works on other groups are: *A Monograph of the Cretaceous Lamellibranchia of England* (1899-1912) by Henry Woods, *Synopsis des Spirobranches (Brachiopodes) Jurassiques Célto-Sonabes* (1915-9) by the Swiss palaeontologist Louis Rollier, and Clarke and Twitchell's *The Mesozoic and Cenozoic*

*Echinodermata of the United States* (1915). Among the major contributions to Mesozoic stratigraphy and entire faunas or floras may be mentioned: Victor Uhlig's *The Fauna of the Spiti Shales* (1903), Carl Renz's *Die mesozoischen Faunen Griechenlands* (1911), G. R. Wieland's *American Fossil Cycads* (1906-16), and E. W. Berry's *The Upper Cretaceous Floras of the World* (1916).

For the Tertiary life especial reference should be made to the contributions on different groups made by Thomas Wayland Vaughan (corals), E. W. Berry (plants), J. A. Cushman (foraminifera), R. T. Jackson (echinoderms), Mary Rathbun (crustaceans), A. Pilsbry (cirripedia), and others in *Contributions to the Geology and Palaeontology of the Canal Zone, Panama, and Geologically Related Areas in Central America and the West Indies* (1919). The bryozoa have been carefully described and beautifully illustrated by Ferdinand Canu and Ray S. Bassler, *North American Early Tertiary Bryozoa* (1920), while the foraminifera have been described in equal detail by Joseph A. Cushman in numerous contributions, and by H. Yabe (1921) and H. Douvillé (1911). For other groups we may note: J. Lambert's *Description des Echinides des terrains néogènes du bassin du Rhône* (1911-6), F. W. Harmer's *The Pliocene Mollusca* (1914-20), and papers by W. H. Dall on the mollusca. A general résumé of the Pleistocene vertebrate and invertebrate life is embodied in F. C. Baker's *The Life of the Pleistocene or Glacial Period* (1920). Stimulating general reviews of the progress of invertebrate palaeontology are the presidential addresses by F. A. Bather, *Fossils and Life*, British Association (1920), by Ruedemann, *The Palaeontology of Arrested Evolution* (1916), and by Clarke, *The Philosophy of Geology and the Order of the State* (1917).

#### PROGRESS IN VERTEBRATE PALAEOONTOLOGY

*Personnel: Advent of the Fourth Generation.*—The principal feature of the period has been the advent of a new generation of explorers and workers in vertebrate palaeontology who, in a sense, constitute a fourth or "20th century" group. Beginning with Cuvier (1769-1832) as founder of the science and leader of the first group, the second group embraced the British anatomists Richard Owen (1804-92) and Thomas Henry Huxley (1825-95), the French leader Albert Gaudry (1827-1908), the Swiss palaeontologist Ludwig Rüttimeyer (1825-95), and the three great Americans, namely, Joseph Leidy (1823-91), Edward Drinker Cope (1840-97), and Othniel C. Marsh (1831-99). These men marshalled the first positive proofs of vertebrate evolution in Europe and America; they worked more or less independently as pioneers and laid the entire foundation of the modern classification of the Vertebrata. The leader of the third group was the Russian, Waldemar Kovalevsky (1842-83), who instituted intensive investigation of mechanical adaptation in relation to natural selection.

Of the same period are A. Smith Woodward (b. 1864) and C. W. Andrews (b. 1866) in England, Marcellin Boule (b. 1861) and Charles Depéret (b. 1854) in France, Louis Dollo (b. 1857) in Belgium, Max Schlosser in Germany, Giovanni Capellini (b. 1833) in Italy, and in America William B. Scott (b. 1858) and Henry Fairfield Osborn (b. 1857). This group includes also Samuel Wendell Williston (1852-1918), and Ramsay H. Traquair (1840-1912). Scott treated chiefly mammals, Williston chiefly reptiles and amphibians, while Osborn treated both mammals and reptiles. The principal accomplishment of this third school has been (1) to conduct world-wide exploration, (2) to correct, co-ordinate and firmly establish the great classifications proposed by the second school and (3) to fill out the details and principles of phylogeny or lines of reptilian, avian and mammalian descent. The leading explorer of this period was John Bell Hatcher (1861-1904), who brought together a large part of the materials for two great monographs of the United States Geological Survey, Osborn's *Titanotheres* and the Hatcher-Lull *Ceratopsia*; he also made the wonderful collection of South American fossils which forms the basis of Scott's monumental memoirs of the Princeton University Expeditions to Patagonia during the years 1896-9. Osborn's monograph *The Titanotheres* (an Eocene-Oligocene family of mammals), twenty-one years in preparation, has been completed but not published; others of his memoirs are the *Equidae of the Oligocene, Miocene and Pliocene of North America* (1918) and *Camarasaurus, Amphicoelias and other Sauropods of Cope* (1921). Williston's monographs are chiefly on the Cretaceous mosasaurs and the archaic Reptilia of the Perm-Trias, to which he made most notable contributions. Of this period were Florentino Ameghino (1854-1911), the dis-

tinguished vertebrate palaeontologist of Argentina and Eberhard Fraas (1862-1915) of Stuttgart. Oliver P. Hay (b. 1846) is also of this group, author of the monograph of the *Fossil Turtles of North America* (1908) and the invaluable *Bibliography and Catalogue of the Fossil Vertebrata of North America* (1902).

To the fourth group of vertebrate palaeontologists belongs the school trained by Professor Osborn in the American Museum of Natural History, of which the senior is William Diller Matthew (b. 1871), Walter Granger (b. 1872), Barnum Brown (b. 1873), William K. Gregory (b. 1876), Richard S. Lull (b. 1867) of Yale University, Lawrence M. Lambe (1863-1919), late of the Canadian Survey, and C. Forster-Cooper, Cambridge University. The chief intensive work of Matthew and Granger has been on the American Eocene mammalian faunas and in aiding Osborn to establish 16 Eocene-Oligocene life zones of North America very closely co-ordinated with corresponding life zones of western Europe. Brown's explorations have added greatly to our knowledge of Cretaceous dinosaurs. Of the same group are the pupils of Williston, of whom the leader is Ermine C. Case (b. 1871), who has contributed treatises on Permian life. At the same time John C. Merriam (b. 1869) has led explorations on the Pacific coast of America and inspired a school of younger workers both in vertebrate and invertebrate palaeontology. In Great Britain D. M. S. Watson (b. 1886) has taken up the work of Owen and Huxley in primary groups of fishes, amphibians and reptiles; in Austria Othenio Abel, a pupil of Dollo, is the great exponent of vertebrate evolution; in Germany Friedrich von Huene and Ferdinand Broili are leaders in saurapsidan palaeontology, other notable palaeontologists of recent years being Franz Drevermann, Ernst Strömer (b. 1871) and Otto Jaekel (b. 1863). At Upsala in Sweden Carl Wiman has inspired a remarkably progressive group of workers, while in Switzerland Hans Georg Stehlin (b. 1870) has continued in the great field of Rüttimeyer.

For the principal contributions by palaeontologists of the third and fourth groups above described, the reader is referred to the Memoirs and Bulletins of the American Museum of Natural History, of the University of California, of the Carnegie Institution of Washington, to the Contributions from the Palaeontological Laboratory (Peabody Museum) of Yale University, to the Memoirs and Catalogues of the British Museum (Natural History), to the Palaeontographica and to the Memoirs of the Société Paléontologique Suisse. It is upon the researches of these workers in field and laboratory that the great synthetic volumes referred to earlier are chiefly founded, and that the following generalisations of modern vertebrate palaeontology are chiefly due.

#### ORIGINS OF THE GREAT VERTEBRATE STOCK AND ITS BRANCHES

*Origin of Chordates.*—No discovery has thus far lessened the gap between the modern Protochordates (*Amphioxus*, tunicates, etc.) and any of the known phyla of invertebrates. Some of the cephalaspis ostracoderms have been cited by Patten as favouring the view that the chordates have been derived from certain arthropods, but such resemblances are ascribed to convergence by Dollo and many others. The earliest ostracoderm remnant actually known is a dermal plate of a genus named *Astraspis* from the Upper Ordovician near Canyon City, Colo.; this represents a new family Astraspididae allied to the Psammosteidae of the Silurian and Devonian (C. R. Eastman, 1917). These chordates, heavily shielded and hence known as *ostracoderms*, were dominant in the Upper Silurian, radiating into six families and many genera, abundant in the Lower Devonian, diminishing in the Middle Devonian and becoming extinct in the Upper Devonian.

*Origin of Fishes.*—The earliest fish remnant actually known is the fin-spined *Onchus* from the Upper Silurian of Scotland, which appears to represent the group of acanthodian sharks, covered with fine quadrate scales like those of ganoids and with a skull structure distinctly elasmobranch. The elasmobranchs (shark and ray types) are still the oldest known gnathostomes or true jaw-bearing vertebrates, constituting (a) one of the four primary

Middle-Cambrian invertebrate fossils, showing diversity of animal life and similarity to recent forms. (U.S. Nat'l Museum, permission of Smithsonian Inst.)

FIG. 6.

Notable vertebrate fossils, complete remains of which have been recently discovered. (By permission of the President of the American Museum of Natural History.)

FIG. 1.—*Deinodon* or *Gorgosaurus*, a mid-Cretaceous carnivorous dinosaur from Alberta, Canada, mounted in running position.

FIG. 2, 2a.—*Struthiomimus*, the "ostrich mimic," a mid-Cretaceous browsing dinosaur, from Alberta, Canada. FIG. 2 shows the complete skeleton in *rigor mortis*, fig. 2a the same skeleton partly restored.

FIG. 3.—*Diatryma*, a gigantic mollusc-eating bird, from the Lower Eocene of Wyoming.

FIG. 4.—*Moropus*, an okapi-like herbivore, from the Lower Miocene of Dakota, related to the *chalicotheres* of Europe and Asia.

FIG. 5.—*Pliotippus*, direct one-toed ancestor of the modern horse, from the Lower Pliocene of Nebraska.

FIG. 6.—*Trilophodon*, direct descendant of *Mastodon angustidens* of Europe and North Africa, Lower Pliocene of Texas.

All the figures are on the same scale.

gnathostome groups, *i.e.*, jawed groups, the others being (*b*) the fringe-finned ganoids (Crossopterygii), (*c*) the ray-finned ganoids and teleosts collectively known as Actinopterygii and (*d*) the lungfishes (Dipnoi). The fossil ancestors of the fringe-finned ganoids have not yet been discovered; so these animals are theoretically traced to unknown cartilaginous fishes of Silurian times. The oldest Crossopterygian actually known is the *Osteolepis macrolepidotus* of the Middle Old Red Sandstone of Scotland. There were two principal periods of adaptive radiation among the Crossopterygii, the first in Middle and Upper Devonian times, the second in Mesozoic times which produced the family Coelacanthidae, from which may have sprung the existing fishes *Polypterus* and *Calamoidichthys* as degenerate offshoots. From the earlier Devonian radiation of the Crossopterygians is traced the theoretic origin of the Dipnoi or lungfishes, on the one hand, and of the oldest known amphibians on the other. The Devonian Crossopterygian skull and fins appear to be "archetypal" to the lungfish type on the one hand, and to the amphibian type on the other. Cope's genius in separating the Actinopterygii is sustained, for there is as yet no fossil evidence of the connection of this group with the Crossopterygii, other than the supposed community of origin in Silurian times. Here the reader should consult the writings of Smith Woodward, Joseph F. Whiteaves, Bashford Dean, William K. Gregory and the synthetic reviews of Osborn (1918) and Lull (1917).

*Origin of Amphibians and First Tetrapods.*—In this epoch-making transition from the fringe-finned fish type to the tetrapodal amphibian and terrestrial type, the prophecies of Huxley, Cope and Baur and other great anatomists of the second and third groups of palaeontologists appear to be fulfilled. The Silurian period marked the parting of the ways among the great primary groups of fishes and the first steps towards the frame of the terrestrial amphibians. Not until the Upper Devonian of Pennsylvania do we find a footprint (*Thinopus antiquus* Marsh), which may be referred to an amphibian tetrapod. The first known actual skeletons occurred in the Coal Measures (Upper Carboniferous) of Europe and America and represented four widely radiating groups. The structural gap separating the earliest tetrapod amphibians and fishes is perhaps the greatest known in the whole range of vertebrate evolution, but all modern authorities agree that the amphibians were probably derived from a Silurian or early Devonian type of fringe-finned fish. Even as far back as the Upper Carboniferous and even in the Lower Carboniferous the Amphibia were adaptively radiating into several orders and numerous families comprising highly specialised forms. During the Carboniferous we find numerous independent phyla of eel-like or burrowing, and of compressed, swimming, as well as of large-bodied, predatory forms. The latter culminate in the gigantic labyrinthodonts of the Triassic. The exact connection of any of these forms with the modern Amphibia (urodeles and Anura) is doubtful. The Anura first appear in the Jurassic, and at the present time they retain many characters reminiscent of such Palaeozoic Amphibia as the branchiosaurs and the *Eryops* group. The urodeles are first known in the genus *Hylaeobatrachus* of the Lower Cretaceous of Europe. Both groups, especially the Anura, appear to have gone through a wide adaptive radiation during the Tertiary. The connection of the modern caecilians with the ancient types is obscure. The reader is referred especially to the contributions of Williston, Case, Watson, Gregory, Broili and the synthetic reviews of Osborn (1918) and Lull (1917).

*Origin of Reptiles.*—The oldest-known reptiles, solid-headed *Cotylosauria* of Cope, are regarded as amphibians which had eliminated the aquatic stages in development, the oldest reptile actually known being the genus *Eosaurus* from the Coal Measures of Ohio. In other words, the cotylosaur reptiles are traceable to solid-headed stegocephalian amphibians, which, in turn, are traceable to solid-headed unknown Crossopterygians of Silurian times. The oldest and most primitive reptiles (*Cotylosauria*) occurring in the Upper Carboniferous and Permian, are thus structurally very close to certain contemporary stegocephalian amphibians. The first great adaptive radiation of the

reptiles into the two grand divisions, the solid-headed (*Cotylosauria*) and the temporal-arched (*Pelycosauria*), began in the Upper Carboniferous and still more widely diverged in Permian times. As early as the Permian, occurs a mammalian-like series of reptiles which exhibits an extensive adaptive radiation and gives off one branch, the *Cynodontia*, which, in turn, survives into Triassic times and clearly approaches the mammalian grade of organisation. From the primary temporal-arched also appear the forerunners of the Mesozoic reptiles, the plesiosaurs, ichthyosaurs, dinosaurs and pterosaurs, widely separated from each other in the Triassic and thus having their branches deep down in the Permian and Carboniferous, each grand division giving rise to an adaptive radiation of its own. These have been traced in detail by such authorities as Andrews, Dollo, Abel, Von Huene, Williston and Osborn.

Here the reader is referred to the writings of Williston, Hatcher, Osborn, Merriam, Lambe, Lull and especially during the past decade to those of Charles W. Gilmore of the United States National Museum, Washington and of Dr. Robert Broom of South Africa, as well as to the synthetic reviews by Osborn (1918) and Lull (1917).

The two greatest achievements of the decade are the clearing up of the relationships of the primitive South African terrestrial Reptilia of the Perm-Trias, beginning with the solid-headed types (pareiasaurs) and ending in their highest expression, the mammal-like types known as *Cynodonts* and *Theriodonts*. The field explorations of Robert Broom and the profound comparative researches of D. M. S. Watson and of William K. Gregory have given us a clear comprehension of the habits and relationships of this first terrestrial radiation group. Williston and Case have covered the same great period in America.

*Origin of Birds.*—Palaeontologists still agree in endorsing Huxley's opinion that birds are "glorified reptiles." The origin of birds, according to recent reviewers such as Osborn and Gregory, brings us close to the two-temporal-arched (*i.e.*, *Diapsida*) reptiles, namely, to the stem which also gave off the dinosaurs, the pterosaurs and the smaller parasuchians (*Euparkeria*). Fossil bird remains are extremely rare. The earliest bird known is the famous *Archaeopteryx* of the Jurassic of Solnhofen, Germany. This is largely a bird, excepting in the tail, the simplicity of the feather arrangement and the possession of teeth. According to the four-winged hypothesis of origin advocated by Beebe, we should some day discover a bird with parachute-like action in both fore and hind limbs. Recent contributions of note on this subject are those of Gerhard Heilmann (1913) and of William Beebe (1915) and the synthetic reviews by Osborn (1918) and Lull (1917).

*Origin of Mammals.*—Evidence has been accumulating rapidly in favour of the theory that the origin of the mammals should be traced to the more progressive terrestrial mammal-like reptiles (the *Cynodontia*) of the Permian and Triassic of South Africa and Europe, as described in the studies of Broom, Watson, Houghton, Osborn and Gregory. Structurally related to these *Cynodonts* are the so-called *Protodonts* of Osborn, *e.g.*, *Dromatherium* and *Microconodon* of the Triassic of North Carolina. But of equal antiquity are the multituberculates, *e.g.*, *Plagiaulax* and *Microlestes*, widely spread over Europe and North America. No substantial additions have been made during the decade to our knowledge of this vague period; readers are referred to the reviews by Osborn (1918) and Lull (1917), also to the recent works of Gregory, *The Orders of Mammals* (1910) and *The Origin and Evolution of the Human Dentition* (1921).

*Origin of Primates and of Man.*—Combined palaeontological and anatomical evidence indicates that the source of the Primates is to be looked for among tree-living insectivorous mammals more or less closely similar to the modern tree shrews (*Tupaiaidae*) of Africa. This view advanced with ability by Gregory is in general accord with the opinion that during the phase of arboreal life many of the psychic and anatomical characters of the Primates were acquired. It was not until the Lower Eocene of North America and of Europe that there appeared undisputed Primates of lemuroid affinity, *e.g.*, notharctids and tarsioids in

America, adapids and tarsioids in Europe. At this time the zoological relation of the two continents was close and it would appear that while the primitive horses were acquiring their cursorial characters on the ground, these primitive lemuroids were acquiring their distinctive characteristics in the trees.

Actual ancestors of the existing *Tarsius* of Madagascar have been found in France (*Pseudoloris*). The attempt of Ameghino to trace the higher Primates to South American types, e.g., *Hammunculus*, appearing in the Lower Miocene of Patagonia, is not supported, because these animals from the first are the true broad-nosed, i.e., platyrrhine, type still characteristic of South America. The Old World division of the catarrhines or narrow-nosed true Primates has been traced to the *Parapithecus*, described by Max Schlosser from the Lower Oligocene of Egypt. *Propliopithecus* is possibly ancestral to the true anthropoid apes and thus possibly related to the ancestors of man himself. Darwin's broad conclusion that man was derived from "some ancient member of the anthropomorphous subgroup of Old World Primates" is fully sustained by anatomical evidence, but the precise lines of descent are still in dispute. Some hold that the human line came from Middle Tertiary anthropoid apes allied to *Dryopithecus* of France and *Sivapithecus* of India, while others (including the present writer) regard the Hominidae as a widely distinct family separated especially by its upright walking gait, by the non-divergence of the great toe, and by the retention of its tool-making thumb. A series of masterly reviews of this whole question has appeared in the American Museum publications from Gregory, whose recent memoir *On the Structure and Relations of Notharctus, an American Eocene Primate* (1920) sums up our present knowledge of this whole subject. (See also EVOLUTION.)

*The Dinosaur Fauna of Alberta, Canada.*—The greatest new achievement in exploration is the revelation of the dinosaur fauna of Alberta in the fossil beds extending along the Red Deer river, which were first made known to science by explorers of the Canadian Geological Survey in 1897, 1898, 1901. The first general review of this wonderful fauna was that of Osborn and Lambe, *On Vertebrata of the Mid-Cretaceous of the North West Territory* (1902), based chiefly on the collections in the Ottawa Museum. The American Museum explorations under Barnum Brown, which extended over 10 years, have resulted in the discovery of the entire fauna of the middle portion of Upper Cretaceous time, a complete revelation especially of the dinosaur world as it approached the height of its adaptive radiation into herbivorous and carnivorous, armoured and defenceless, swift-moving and slow-moving types, which severally imitate more or less fully the long subsequent adaptive radiation of the mammals. In 1914 the Canadians renewed exploration, so that at present the Ottawa and Toronto museums have rich collections, part of which has been described by the late Lawrence M. Lambe, while Osborn, Barnum Brown and W. A. Parks have also made known a part of this wonderful fauna. Two of the greatest extremes of adaptation, namely, *Deinodon* or *Gorgosaurus* and *Struthiomimus*, are figured in the accompanying Plate II. In the same plate appear some of the outstanding American discoveries of the decade.

#### NEW DISCOVERIES AMONG FOSSIL VERTEBRATES

*Fossil Fishes.*—Dr. A. Smith Woodward's *Fossil Fishes of the English Wealden and Purbeck* (1915-8) is a beautifully illustrated memoir of the most thorough, systematic type, well sustaining the traditions set by Traquair and by the author himself in earlier works. The period dealt with affords an interesting cross-section of the stream of piscine evolution at a time when many of the old Mesozoic ganoids were dying out and the teleost fishes were beginning their remarkable expansion. Other important systematic memoirs are those by Stolley on the ganoids of the German Muschelkalk (1920), and by Stensiö (1921) on Triassic fishes from Spitsbergen. The latter memoirs contain a wealth of material of great morphological interest concerning the early stages in the evolution of the skull of the fringe-finned and ray-finned ganoid fishes; this discussion also throws light on the

origin of certain elements in the skull of higher vertebrates. In this connection should be mentioned the brief but highly important paper on *Eusthenopteron* by W. L. Bryant (1919). This fringe-finned ganoid is of particular interest because the construction of its skull and paired limbs approaches the type which may be expected in the piscine ancestors of the land-living vertebrates. The arrangement of the elements on the under side of the skull of this fish raises morphological questions of wide general interest. Papers by Watson and Day (1916) and by Gregory (1915, 1920) deal with the ancestral relations of these fringe-finned ganoids with the land-living vertebrates (tetrapods).

The swarming fauna of Devonian arthrodires, ptyctodonts, cladodonts and other archaic fossil fishes from the vicinity of Buffalo, N.Y., is ably described by Bryant and Hussakof in their *Catalog of the Fossil Fishes in the Museum of the Buffalo Society of Natural Sciences* (1918). A serious difficulty encountered by all students of recent and fossil fishes is the getting in contact with the vast and scattered literature of the subject. The great *Bibliography of Fishes* by Bashford Dean and his associates Eastman and E. W. Gudger (1917) will undoubtedly stimulate research in this field.

*Fossil Amphibians.*—The outstanding publications in this field are *The Coal Measures Amphibia of North America*, by R. L. Moodie (1916), and a memoir on *The Structure, Evolution and Origin of the Amphibia*, by D. M. S. Watson (1919). Moodie's memoir is a valuable description and compilation of the extensive and varied fauna of swamp-living amphibians of the American Coal Measures. Watson's memoir is a brilliant and highly original contribution to the classification and phylogeny of the labyrinthodonts. Much detailed work on fossil amphibians appears in papers by Von Huene, Broom, Williston, Van Hoepen, Haughton and others.

*Stem Reptiles.*—In the field of the oldest reptiles, those of the Carboniferous and Permian, perhaps the most important contributions are those by S. W. Williston and D. M. S. Watson. The former, in his paper on *The Phylogeny and Classification of the Reptiles* (1917), traces the rise of the common amphibian-reptilian stock through the "Protopoda," which are so far known only from certain footprints of Upper Devonian age. According to Williston, who built on Osborn's system of 1903-4, the primitive reptilian stock early divided into the following series:—

*Anapsida* (Cotylosauria and their specialised descendants, the modern tortoises and turtles).

*Synapsida* (Theromorpha or pelycosaurs, etc.; Therapsida, or mammal-like reptiles, the latter giving rise to the mammals; plesiosaurs).

*Diapsida* (reptiles with two temporal arches, such as crocodiles, dinosaurs, rhynchocephalians; this stock gave rise to birds).

*Parapsida* (including the proganosaurs, ichthyosaurs, lizards, mosasaurs, snakes).

Watson (1917), in his *Sketch Classification of the Pre-Jurassic Tetrapod Vertebrates*, assigns a high value in classification to the characters of the brain case. A general and conservative classification of the early reptiles is given by W. K. Gregory (1920). The most primitive known reptile, *Seymouria*, from the Permian-Carboniferous of Texas, almost bridges the gap between the Amphibia and the Reptilia. Watson (1919) gives a morphological description of this reptile, accompanied by valuable figures and reconstructions of the skull and skeleton.

The habits and environments of the teeming reptilian and amphibian faunas of the Permian-Carboniferous of North America are intensively considered in a memoir by E. C. Case (1919), which also deals with the stratigraphy, climatology and palaeogeography of the late Palaeozoic.

*Mammal-like Reptiles.*—In no other field of fossil reptiles has the progress of discovery been more satisfactory than in that of the mammal-like reptiles of South Africa, as set forth in numerous papers, especially by Watson (1913-4), Haughton (1918), Broom (1913-4), Van Hoepen and others. The relationships of these animals with other reptiles and with the mammals have been reviewed by W. K. Gregory (1920-1).

*Marine Reptiles.*—These have always been of great interest on account of their secondary adaptations to aquatic life which have

been ably discussed by Abel (1912, 1919). One of the outstanding contributions of new material in this field is the *British Museum Catalogue of Marine Reptiles of the Oxford Clay*, by C. W. Andrews (1910-3). The origin and relationships of the plesiosaurs and their allies are treated by Von Huene (1921).<sup>(11)</sup>

**Dinosaurs.**—The Triassic dinosaurs of Europe are of particular interest because some of them tend to connect the very diverse carnivorous and herbivorous saurischian dinosaurs of later ages. Here the leading author is F. von Huene, in a long series of papers and memoirs. *Plateosaurus*, perhaps the most primitive of these reptiles, has been fully described both by von Huene and by Jaekel (1913-6). Primitive dinosaurs from the summit of the Karroo series in South Africa (*Gryponyx*, *Massospondylus*, etc.) are described by Broom and Haughton. During the long ages of the Jurassic the gigantic sauropodous dinosaurs attained their maximum in size and specialisation. The leading feature in this field is the description of the strange and monstrous dinosaurs of the Tendaguru fauna of East Africa in the collections of the Berlin Museum, by Janensch (1914). One of the most remarkable of the North American sauropods is the genus *Camarasaurus*, which has been intensively described by Osborn and Mook (1921). *Barosaurus*, a gigantic relative of *Diplodocus*, with a tremendously heavy neck, has been described by R. S. Lull (1919). *Tyrannosaurus*, the greatest carnivorous reptile of all time, and *Struthiomimus*, a contemporaneous ostrich-like dinosaur, have been described by Osborn (1912-9). The highly varied and grotesque armoured dinosaurs, namely, the Ceratopsia and related groups, have been the subject of numerous papers by Gilmore, Brown, Lambe and others.

**Pterosaurs.**—The pterosaurs, or flying reptiles, have continued to excite the interest of students of flight, such as Abel (1912) Watson and Hankin (1914), Arthaber (1921). The greatest flying reptile, *Pteranodon*, is the subject of a memoir by Eaton (1910) of Yale University.

**Chelonians.**—An important memoir by O. Jaekel (1913-6) describes the skull, skeleton, carapace and plastron of *Triassochelys dux* from the Upper Triassic of Germany. Although widely differentiated from all other orders this reptile was the most primitive of all known chelonians. Of even greater interest is the *Eumotosaurus* from the Permian of South Africa, which Watson (1914) describes as a veritable "archichelone."

**Fossil Birds.**—*Diatryma*, a gigantic ground bird from the Lower Eocene of Wyoming, has been described by W. D. Matthew and W. Granger (1917) from a nearly complete skeleton, which is a most rare and valuable fossil. This bird, which has no near relatives, was about seven feet high and of massive proportions, with an enormous head and great compressed beak. The wings were vestigial. This high degree of specialisation at such an early epoch indicates that the modernised groups of birds were differentiated during the latter part of the Age of Reptiles.

**Monographs on Special Groups of Tertiary Mammals.**—The fossil mammals of the basal and Lower Eocene of the western United States are represented in the American Museum of Natural History by collections numbering many thousands of specimens which are being described jointly by Matthew and Granger (1915). Besides describing many new or little known forms these authors also deal with the relationships and morphology of the various groups of early placental mammals. In the paper dealing with the edentates and their relatives, the "palaeanodonts," Matthew (1918) advances the view that the modern Pholidota (Pangolins) are an offshoot of the primitive "palaeanodonts" of the Lower Eocene. Other papers of the same series cover the Creodonts, Insectivores and Primates.

Several mid-Tertiary mammalian groups, such as chalicotheres, entelodonts and the diceratheres, have been revised in the publications of the Carnegie Museum, Pittsburgh, by W. J. Holland and by O. A. Peterson (see MONGOLIA, PALAEOONTOLOGIC DISCOVERIES IN). (H. F. O.)

#### SOME NEW DEVELOPMENTS.

In recent years two aspects of palaeontological work have been actively pursued. The explorations carried out in north-

eastern Asia by the American Museum, supplemented by those conducted jointly by the Chinese Geological Survey and the University of Uppsala (Sweden), have added enormously to our knowledge of the history of the geographical distribution both of mammals and dinosaurs, and will when carried to their completion leave Africa as the least known land which can have played an important part in the evolution of placental mammals.

An obscure region in the life of North America is being rapidly cleared up by the research of Matthew on the Upper Miocene and Pliocene faunas. In Europe work by Stehlin and others is gradually giving us an accurate knowledge of the structure and relationships of the older tertiary mammals, whilst those of the Pleistocene are at last receiving adequate treatment. The long known fossils of the Sivalik hills in India have been assigned to their true horizons by G. E. Pilgrim, whose collections from rocks of earlier date than those found by former workers have added many most interesting anthropoid apes to our knowledge, and will much modify our ideas of the phylogeny of some groups of mammals. From deposits in Baluchistan of Upper Oligocene age Pilgrim and Foster Cooper have made great collections mainly of anthrocotheres and rhinoceroses, the latter worker having obtained limbs and vertebrae of an extraordinary rhinoceros Baluchitherium. Subsequently Borissiak obtained from Turgai, Turkestan, a fragmentary skull, many vertebrae and ribs and the limbs of a closely similar or identical animal, which has now been mounted in Leningrad. Finally, the American Museum obtained a skull of the same type from Mongolia. These materials allow of a reconstruction of the complete skeleton. The animal so obtained is a gigantic rhinoceros, with a skull five feet in length, hornless and very long and narrow, set on an enormous flexible neck. The immense body is carried on pillar-like legs, the tridactyl hands and feet being extraordinarily elongated, so that the creature walked entirely on its toes like a horse. The height at the withers is estimated at 13 ft., considerably more than that of any living elephant, and more than twice that of the tallest other rhinoceros known.

Pilgrim has recently described a fragmentary but most important mammal fauna of Upper Eocene age from Burma remarkable in that it contains teeth of the first Titanotheres found in Asia, animals whose occurrence here is explained by the many forms found still more recently in Mongolia.

In Africa little has been done, but very fragmentary remains of Miocene mammals found near Victoria Nyanza have been described by Andrews, and others from German South West Africa by Strömer. Dietrich and Andrews have described small late Pliocene faunas from the Lakes region of Central Africa. Finally, in his last paper, C. W. Andrews recorded the occurrence of a Chalicotherium in the Pleistocene fauna of Kenya.

Amongst reptiles the most important discoveries of new materials of which accounts have been published are those of the German expeditions to Tendaguru, which have obtained splendid materials of Sauropodous dinosaurs and of a small Stegosaur; of the American Museum in Mongolia (*q.v.*) and of Strömer in the Cretaceous of the Libyan desert. Strömer has described two most remarkable crocodiles, one with a very small, short-snouted and deep skull, the other with an enormously elongated flat head, presenting some resemblance superficially to a pelican's bill. Thus the work of exploration has been most actively pursued, but results of no less importance have come from the examination by modern technical methods of old materials. This work has in the main been directed to the solution, often by a co-ordination of palaeontological and embryological researches, of certain problems of morphology. It is work of a new type initiated by Dr. R. Broom.

Prof. J. Kiaer of Christiania has published a most detailed description of three genera of Anapsida (*q.v.*) from the Devonian rocks of Norway. The animals of this group, formerly known almost entirely from material from the rocks of the same age in the south of Scotland, prove to possess a heterocercal tail of unique type in which the muscular end of the body passes downward into the lower caudal lobe, instead of, as in all fishes, into the upper. They have a pair of large eyes, between which, on

the dorsal surface of the head, is a single median nostril, placed immediately in front of a foramen for a pineal eye. The whole arrangement is remarkably like that which exists in the lamprey. The mouth, however, appears to be arranged for biting, and in no way recalls that of *Pteromyzon*.

Kiaer shows that the external branchial openings are small pores and that they may vary in number from seven to 13, as in hagfish. Dr. Stensiö, of Stockholm, has recently shown that the lateral line system on the body armour of heterostraci does not conform to that found in all fish, but is comparable with that of cyclostomes and appears to be inclined to group those forms, which have paired nostrils, with the Anapsida and Cyclostomes, the whole forming, with the Osteostraci, a group of bony vertebrates more primitive in their structure than the true fishes. Dr. Stensiö has also revolutionised our knowledge of the structure and understanding of the relationships of the long-known Arthrodeires. He shows that *Macropetalichthys*, a form known for some 60 years, had a fully ossified braincase so thick and well preserved that he has been able to determine not only the shape of the brain cavity but also the exact distribution of some of the cranial nerves and blood vessels. There is no doubt that in all points which can be determined the form agrees with the elasmobranchs, and differs from all bony fish. The possibility is opened that the living cartilaginous fish are the descendants of bony ancestors. Sir Arthur Smith Woodward has been able to show that another arthrodeire *Deinichthys* had ossifications associated with the palatoquadrate cartilage.

Among bony fish proper the most important work has been the description by Bryant, Stensiö and Watson of the details of the structure of the braincase, dermal skull and palate of certain Osteolepids and of the Coelacanth which prove to be their direct descendants. The most striking feature of these fish is the presence in them of a long unossified region between the basisphenoid and the basioccipital and the consequent separation of the well ossified braincase into two distinct halves. But of more general interest is the occurrence in all Osteolepids and in the oldest known Coelacanth, of an olfactory organ of amphibian type, opening to the surface of the skull by an anterior and to the palate by a posterior nostril. The structure of several carboniferous dipnoi has been described by Watson and Gill.

The palaeoniscid fish, which are the oldest representatives of the Actinopterygii, have become much better known, the structure of the braincase, palate and hyobranchial apparatus having been described by Watson and Stensiö in Carboniferous and Triassic forms. The braincases prove to be typically actinopterygian, possessing large eye muscle and aortic canals.

Stensiö has given a complete account of the osteology of the head in the remarkably elongated Saurichthids, a mainly Triassic group of fish, which prove, as A. S. Woodward long ago suggested, to be direct and relatively little advanced derivatives of the palaeoniscids. Henning has described as *Chondrosteus Hindenburgi*, a magnificent sturgeon some 12 ft. in length from the Upper Lias of Württemberg. Watson has described the structure of the Carboniferous Labyrinthodonts, all of which belong to the grade Embolomeri. In the structure of their skulls these animals prove to be directly comparable with Osteolepid fish on the one hand and with the reptile *Seymouria* on the other, whilst they include the ancestors of the later Labyrinthodonts, the course of whose evolution as determined by Watson has been confirmed by the work of Haughton.

Amongst reptiles the most interesting work of a morphological type has been concerned with the evolution of the skeleton of the limbs considered as one part of a machine the remainder of which consists of the muscles. Watson, W. K. Gregory and his students and Romer have reconstructed from the indication of muscle insertions on fossil bones the complete limb musculature of several Permian and Triassic reptiles, and shown that these exhibit a steady improvement of mechanical efficiency as the evolutionary series are traced upward. (D. M. S. W.)

**PALAMÂS, KOSTES** (1859- ), Greek poet, was born at Patras in 1859. In 1875 he went to Athens to study law and there came under the influence of the "popular," as opposed to the "purist" school of Greek, and, after several years of journalism, published in 1886 his first poetical work, *The Songs of My Country*, followed in 1889 by the *Hymn to Athena*. Appointed in 1897 secretary to the University of Athens, he was able to devote all his spare energies to poetry, while he had already issued a prose *Essay on Krystallis* (1894), in which he contrasted philosophic with descriptive poets. After the publication of *Iambus and Anapaests* and *The Grave* (1898), a series of elegies on his son's death, he became the recognised chief of the "popular" party in literature, whose organ in the Press was the review, *Nowmas*. At that period the "language question" penetrated even politics, leading to the "Gospel Riots" of 1901 and the fall of the Cabinet over the translation of the *Oresteia* in 1903. Palamâs, who described himself in *The Twelve Lays of the Gipsy* as "the poet of my age and race," was considered by his admirers to be the successor of Solomos, while some critics have found in him the obscurity of Browning. Later he produced the poem on Byron, recited at the Byron centenary at Athens in 1924, and *Five Syllables and the Pathetic Whispers* (1925).

See *Poems by Kostas Palamâs*, selected and rendered into English by Th. Ph. Stephanides and G. C. Katsimbali (1925).

**PALEOLOGUE, MAURICE GEORGES** (1859- ), French diplomat and writer, was born in Paris Jan. 13 1859. He entered the diplomatic service at an early age and went successively to Tangier, Rome, Germany, the East, Korea and Bulgaria. He became in 1909 deputy-director and in 1911 director of affairs in the Foreign Office. Shortly before the outbreak of the World War he was appointed ambassador to St. Petersburg (Leningrad) and retained this post until the Bolshevik revolution towards the end of 1917. He successfully exerted great efforts to consolidate the Franco-Russian alliance and to ensure the most effective military action on the part of Russia during the period of hostilities. In 1920 he was for a few months secretary-general of the Ministry of Foreign Affairs and afterwards tendered his resignation. M. Paléologue published in 1921-2, under the title of *La Russie des Tsars pendant la grande guerre*, some interesting records of his diplomatic experiences in St. Petersburg. Among his other publications are historical works; literary criticisms, notably on Vauvenargues and Alfred de Vigny; accounts of his impressions of China and Italy and several novels.

Recent works include: *Le Roman Tragique de l'Empereur Alexandre II.* (1923); *Talleyrand Metternich Chateaubriand* (1924); *An Ambassador's Memoirs* (tr. by F. A. Holt, 1923-5).

**PALESTINE** (see 20.600), a territory administered by the British Govt. under a mandate from the League of Nations which came officially into operation on Sept. 29 1923. Bounded on the north by the French sphere of Syria, on the west by the Mediterranean, and on the south by Egyptian and Hejaz territory. On the east is Transjordan (q.v.) which is included in the Mandate. The area of Palestine, excluding Transjordan, is something over 9,000 sq. m. of which about half is cultivable. The population at the outbreak of War in 1914 was estimated at 689,281 (534,615 Moslems, 70,000 Christians, 84,666 Jews). This was considerably diminished by war, famine, disease and exile. On Dec. 31 1925 the parallel figures exclusive of the nomadic tribes were 762,316 (522,137 Moslems, 74,624 Christians, 157,188 Jews, 8,367 others). Since the opening of immigration with the pro-

mulgation of the Immigration Ordinance (1920) 78,567 immigrants (528 Moslems, 1,863 Christians 76,176 Jews) have entered Palestine.

### I. POLITICAL HISTORY

**Under Ottoman Rule.**—Palestine under the Ottoman Govt. was an integral portion of Syria, although the Sanjaq of Jerusalem, owing to its peculiar problems and importance, was governed by a Mutasarref referring directly to Constantinople. Owing to the economic stagnation and financial strain which affected the whole Ottoman Empire in consequence of the Italian (1911-2) and Balkan (1912-3) wars, Palestine, was unable to develop herself in any way before the outbreak of the World War. Before 1913 autonomy in the Imperial Provinces extended in practice only to the right of making recommendations. The Ottoman constitution of 1908 had awakened new hopes, and in Syria and Palestine particularly so widespread a movement began in favour of decentralisation that the Turkish Govt. thought it wise to pass the Provisional Vilayet Laws of 1913 and 1914, granting real Local Government powers. It is difficult to conjecture now to what extent a naturally intelligent people, discouraged and enfeebled by four centuries of gross misgovernment, might have been helped by plans which were in fact cut short by the War and replaced by the tyranny of Jemal Pasha.

**British Military Occupation.**—The British occupation, established after the conquest of the country by the British forces under General Allenby in 1917, found a depleted population, the townspeople distressed, much cultivated land untillied, stocks of cattle and horses almost non-existent, orange groves ruined by lack of irrigation and commerce at a standstill. Immediately on the occupation of Jerusalem (Dec. 11 1917), a military administration was set up, at first under Brigadier-General Clayton, Chief Political Officer to General Allenby, as Chief Administrator; who was followed by Major-Generals Money, Watson and Bols, with military governors at Jerusalem and elsewhere; food was hurried up by military transport for the populace, and merchants were permitted to import goods from Egypt by the military railway. In accordance with General Allenby's proclamation, all existing rights in Holy Places were respected and maintained; further, the income of the Moslem Wakfs (pious foundations) was used exclusively for the Moslem beneficiaries in Palestine instead of being drained away to Constantinople. The administration was, from the outset, financially self-supporting. A local police force was built up, schools and law courts were re-opened, and, in April 1918, a water supply for Jerusalem, utilising springs employed for the same purpose in the days of Herod and Pontius Pilate, was installed.

**Zionism.**—On Nov. 2 1917, some five weeks before Lord Allenby's entry into Jerusalem, Earl (then Mr. Arthur) Balfour, at that time Foreign Secretary, had made on behalf of H.M. Govt. the following historic declaration:—

His Majesty's Government view with favour the establishment in Palestine of a National Home for the Jewish people, and will use their best endeavours to facilitate the achievement of that object, it being understood that nothing shall be done which may prejudice the civil and religious rights of existing non-Jewish communities in Palestine, or the rights and political status enjoyed by the Jews in any other country.

The declaration was endorsed by the principal Allied Powers and embodied in the Treaty of Sèvres, where it was provided that the country should be entrusted to a Mandatory Power with a mandate to be approved by the League of Nations. After the Balfour declaration the Zionist Organisation sent a Commission, subsequently constituted as a part of the Zionist Executive, to Palestine to act as a link between the British authorities and the Jewish population. This was developed so as to take charge of the larger Jewish interests, colonisation, immigration, and education in Palestine. The military administration was, from its inception, assailed with demands on the one hand for an immediate and practical interpretation of the Balfour declaration, and on the other for a policy of entire negation until such time as that instrument should have been incorporated into some sort of Mandate formally adopted by the Powers.

The Home Govt. not being in a position to issue even general instructions, the administration, left in a situation without precedent more or less to its own resources, was limited by the legal necessity of governing the country under Ottoman Codes amplified by enactments under military law, according to the "laws and usages of war." Even so, however, two notable and, in the circumstances, exceptional steps were taken. Hebrew was recog-

nised with English and Arabic as the third official language, as, with Latin and Greek, it had been in the time of Christ, and considerable agricultural loans were advanced to land-owners. At the same time various oppressive small taxes were abolished. The Jerusalem Chamber of Commerce was established and followed by others elsewhere. The unsightly wall which had been built across Constantine's Basilica of the Nativity in Bethlehem

was removed. Early in 1920 the Moslem Nebi Musa celebrations were exploited as a manifestation of Arab national sentiment against the Zionist Jews, many of whose recent immigrants had excited animosity by unwise and tactless propaganda. Riots took place on April 4 and 5 in Jerusalem and raids were made upon Beisan and the British Garrison at Semakh.

On July 1 1920 a civil government was established with Sir Herbert Samuel as the first high commissioner of Palestine. But mutual suspicion continued, and with it further incidents. For the establishment of a civil government and the subsequent promulgation of the Mandate only brought to a head the difficulties of interpreting even the expanded mandatory text of the declaration, and with them the doubts of Arabs, Zionists and Jews throughout the World. The Jerusalem riots of 1920 were succeeded next year by a more serious outbreak in Jaffa and again by disturbances in the capital on the fourth anniversary of the declaration.<sup>1</sup> The high commissioner, after two years' experience of conditions in Palestine, returned to London in 1922 in order to represent to ministers the necessity of publishing some statement informing all parties concerned more precisely what was, and still more what was not, the Government's interpretation of the Balfour declaration.

This statement, which was issued as a White Paper by Mr. Churchill, the Colonial Secretary, and whose policy was formally and publicly accepted by the Zionist Organisation, explicitly disclaims the intention either of creating a wholly Jewish Palestine or of contemplating the disappearance or the subordination of the Arab population, language or culture.

The nationality to be acquired by all citizens of Palestine, whether Jews or non-Jews, whether for purposes of internal law or international status would be Palestinian and nothing else. . . . But in order that the Jewish community (in Palestine) should have the best prospect of free development it is essential that it should know that it is in Palestine as of right and not on sufferance. That is the reason why it is necessary that the existence of a Jewish National Home in Palestine should be internationally guaranteed. . . .

The statement was rejected by the Palestine Arab Delegation, then representing the Arab cause in London, partly because they were at the time committed to demands involving almost a retraction of the Mandate and partly from an instinctive reasoning that the policy even so enunciated might ultimately render Palestine Arabs of secondary interest and importance in their own country. This new definition has nevertheless considerably affected Arab opinion, and, as it has been integrally maintained by successive Labour and Conservative Cabinets, in each of whom respectively high hopes had been placed by Zionist and Arab "revisionists," it has gone far to convince both of the futility of further agitation.

*Constitution.*—Three months after the beginning of the Civil Govt. the high commissioner established a nominated advisory council, consisting of 10 British officials and 10 Palestinians—seven Arabs (four Moslem and three Christian) and three Jews. Later, on the promulgation of the Mandate, it was thought advisable to confer upon Palestine a more representative constitution, and an order in council was issued in 1922, providing for the creation of a legislative council consisting of the high commissioner and 22 other members, of whom 10 were to be officials and 12 elected. The elected members were to be eight Moslems, two Jews and two Christians.

A virtual boycott of the elections on the part of the Arab population rendered these proposals abortive, and invitations were issued to leading Palestinians with a view to restoring the nominated advisory council, in the same proportion as had been intended for the elected council. The invitations were accepted, but subsequently, under pressure of extremist agitation, seven of the 10 who had accepted begged leave to retire. In July 1923 the high commissioner was instructed to offer to the Arab population equal representation with the Zionists by means of an Arab agency with functions analogous to those of the Zionist executive. This was unanimously refused, as an assumption

that they needed an embassy in their own home, by Arab leaders of all sections of opinion. The present system of government is that ordinances are considered first by the high commissioner in executive council, next, after receiving the provisional approval of the Colonial Secretary, submitted to the advisory council consisting of 10 senior officials, and then published in the official Gazette; but do not, save in rare cases of special urgency, become law until at least one month after publication, so that interests affected may be given the opportunity of expressing their views. This they often do with effect.

*Religion.*—Complete liberty of religion prevails in Palestine. In certain matters of internal organisation, however, action has been taken to assist the communities. A purely Moslem authority has been constituted for the control of Moslem religious endowments (Wakfs) and for appointment of judges in the Moslem religious courts. To this authority, represented by an elected council, the Government has transferred certain wealthy endowments sequestrated 80 years ago by the Turks. The Council has collected large sums for the restoration, now in progress, of the Haram al-Sharif in Jerusalem, and has established a Moslem theological college and an orphanage. The Orthodox Patriarchate of Jerusalem, torn by dissensions both between the Patriarch and his Synod and with the Orthodox Arab congregation, and crippled by debts, has seen the authority of its Patriarch vindicated by a commission of inquiry, and its economic restoration begun by a financial commission, both appointed by the Government. The valuable Russian ecclesiastical properties in Jerusalem and other centres have been placed, pending final decision as to their juridical ownership, rendered ambiguous by various decrees of the Soviet Govt. and as a general measure of protection against secularisation and alienation, under an official trustee. These inevitable but unconnected actions have been in some quarters inaccurately represented as a marshalling of Orthodoxy by Protestantism against Rome. The Jewish community had possessed no recognised ecclesiastical organisation. The Government assembled in 1921 a conference of leading Jews from all parts of Palestine. Two joint chief Rabbis were elected; a Rabbinical Council was established and officially recognised. The lay community was also organised into central and local councils. In 1924 the French Protectorate of Latin Holy Places was withdrawn by the Vatican.

*Police.*—The police force, composed of both Arabs and Jews, has during the past seven years greatly improved in discipline, efficiency and reliability; and brigands, from biblical times the traditional terror of the highways, have been almost exterminated. A unit of Palestinian gendarmerie was raised in 1921 consisting of 500 N.C.O.'s and men (Arabs, Jews and Circassians) under British officers. This force was entrusted with the defence and policing of the land frontier of Palestine. In April 1922 a force of British gendarmerie, consisting of 43 officers and 700 other ranks, reduced later by one third, was enlisted in Ireland and proved an admirable reinforcement to the other two bodies. The last Imperial regiment (sent to Palestine not at the request of the administration but by desire of the War Office) has (1926) left the country and the total garrison, not supported from the resources of the country, consists of one flight of aeroplanes and two sections of armoured cars. Some of the aeroplanes are stationed in Transjordan, and the cost to the British taxpayer (estimated for 1925-6 at £E.640,600) excluding expenditure in Transjordan, has been steadily, and may be still further reduced. Apart from the cost of the garrison, there is not and has never been any grant from the British Exchequer in aid of the civil administration of Palestine. A re-organisation of the civil forces (police, Palestine and British gendarmerie) has just taken place which will increase the British strength of the police. Both British and Palestine divisions of the gendarmerie have been disbanded, and a new frontier force constituted for employment in Palestine and Transjordan also.

*Justice.*—The system of justice originally established by the military administration has been amended where necessary. British judges under a Chief Justice preside over the two sections of the Court of Appeal, four district courts and two land courts.

<sup>1</sup> For the general atmosphere and "psychology" of these events the reader is referred to the report of the commission of enquiry (Cmd. 1549, 1921.)

All other judges and magistrates are Palestinians drawn impartially from among the qualified members of the three religious communities. Cases of religious law and personal status are still judged as under the Turkish régime by the special tribunals of the several creeds. Ottoman law, amended by ordinances of the administration, remains the foundation of the legal system.

## II. FINANCIAL AND ECONOMIC DEVELOPMENT

**Finance.**—In 1923 there was a budgetary deficit of ££.725,000. As a result of drastic economies, the position was retrieved in 1924, and resulted in a surplus of approximately ££.263,000.

### *Revenue and Expenditure*

| Year   | Revenue    | Expenditure | Surplus | Deficit |
|--------|------------|-------------|---------|---------|
|        | ££         | ££          | ££      | ££      |
| 1920-1 | 1,422,208  | 1,227,056   | 195,152 |         |
| 1921-2 | 1,997,522  | 1,881,108   | 116,414 |         |
| 1922-3 | 1,764,585  | 1,837,173   |         | 72,588  |
| 1923-4 | 1,633,893  | 1,633,227   | 666     |         |
| 1924-5 | 2,101,072  | 1,806,660   | 294,412 |         |
|        | 8,919,280. | 8,385,224   | 606,644 | 72,588  |

The rate of the tithe has since been reduced from 12½%, the Turkish figure, to 10%, thus relieving the agriculturist at a single step of one-fifth of the weight of the tax. Palestine has hitherto had the use, free of payment, of the main line of railway, and of certain other works constructed by the British army for military purposes during the War.

**Communications.**—There are 600 km. of metalled main roads in Palestine and 600 km. of secondary roads, serving 177 villages, of which 280 km. have been constructed or rebuilt since the establishment of the civil administration. Many hundreds of miles of tracks connecting scattered villages and settlements are used by motor and other wheeled traffic in the dry weather. In 1914 there was only one motor car in Palestine; there are now over 1,000, including more than 600 within the municipal area of Jerusalem. The military railway constructed by the Army across the Sinai desert has been brought under the management of the Palestine Railway Department. A train service is efficiently run from Egypt to Haifa, from Jaffa to Jerusalem and from Haifa to Syria. Before the War the postal services were maintained largely by separate agencies of European Powers; telegraphs were restricted; telephones unknown. There are now frequent daily deliveries of letters; 34 telegraph offices, 31 public telephone exchanges, and trunk lines to all parts of the country and Egypt answers calls in English, Arabic and Hebrew at any hour of the day and night.

**Public Health.**—The department of health has directed intensive and successful efforts against malaria, with the co-operation of voluntary organisations, notably the Rockefeller Foundation, by whom much necessary hospital provision is afforded, except for infectious disease, for dealing with which the department is responsible. In combating trachoma, in which the British Ophthalmic Hospital of St. John of Jerusalem plays a chief part, 50,000 school children are annually inspected; infant welfare centres have been established, largely by non-official bodies, in eight towns; 20 nurses and 38 midwives have qualified in the Department's training centres and 82 nurses and four midwives in voluntary institutions. Vaccines are prepared and quarantine and disinfection of immigrants and pilgrims returning from Mecca is carried out. Free treatment is provided against rabies. The death-rate for the country is 22.53 in towns and 28.01 in districts, while the birth-rate is 47.40 and 53.68 respectively. The infantile mortality rate is 184.43 per thousand.

**Education.**—There are 315 Government and 489 non-Government schools. The schools maintained by Government include two training colleges, one for men and one for women. Altogether about 50,000 children, aged from 5 to 14, and about 8,800 aged from 15 to 18, receive a measure of education; being 31% of the children between the ages of 5 and 14, and 26% of those between 15 and 18. The Palestine Zionist executive spends some ££.100,000 annually on Jewish education. English, Scottish and foreign Missionary Societies also maintain schools.

**Archæology.**—In 1918 the military governor of Jerusalem, in order to preserve the antiquities of the district, issued and enforced certain public orders; and, to organise public opinion, established the Jerusalem Society, an international and non-sectarian body, in which all communities and most learned societies participate through their leading members. The society encourages arts and crafts, employs a qualified architect and town planner to protect the amenities of the old and advise on the development of the new city, and has collected in subscriptions some ££.15,000. A Department of Antiquities was established in 1920, by which 2,860 historical sites have been registered and are being inspected. A central museum has

been organised in Jerusalem. Work in the field has been undertaken by British, French, American and German schools of archaeology and by a Palestine Jewish Archaeological Society. A Neanderthal skull was discovered in 1925 at Tabgha by the British School.

**Assistance to Farmers.**—The ££.562,000 advanced by the military administration, mostly in small loans on security of land and crops, enabled peasants to buy animals and seed, and in many ways to recover from the devastation of the War. Subsequently a Department of Agriculture and Forests was established, which gives instructions in villages and promotes the use of improved instruments and methods. It assists the farmer in dealing with animal diseases and plant pests, fumigates his orange trees if affected by scale, protects his cattle from imported diseases by quarantine and veterinary control; has planted about one million trees, and, through its nurseries, has facilitated plantation by others. Altogether, four or five million timber and fruit trees have been planted in these years in Palestine. Jewish agricultural settlements came into existence, during the past half century. Many were formed on uncultivated and unpromising land which has been transformed into flourishing plantations. The settlers have drained swamps, planted eucalyptus and pines, cultivated vine and almond and developed the orange trade of Jaffa.

At the outbreak of war there were 44 settlements of 87,800 acres. There are at present (1926) about 100 covering an area of 220,000 acres (6% of the cultivable area of Palestine) and supporting a population of about 24,000. Of the older settlements most were founded or largely assisted by Baron Edmond de Rothschild or the Jewish Colonisation Association acting as his agent; the later mostly by the Zionist Organisation. Largely owing to the lifework of Eliezer Ben Yahuda, a practical visionary of genius, Hebrew is definitely established as the vernacular as well as the literary language of Palestinian Jewry. The revival of Hebrew culture found in 1925 concrete expression in the formal opening by the Earl of Balfour of the Hebrew University upon Mount Scopus. Hardly less remarkable is the development in 18 years of Tel-Aviv from the suburb into the rival of Jaffa.

**Natural Resources and Industry.**—Before the War, industries were almost non-existent. A few soap and oil factories at Nablus and elsewhere, Baron Edmond de Rothschild's wine factories, and some hand industries, such as the Bethlehem mother-of-pearl, represented the sum of local manufacture. Largely owing to Jewish enterprise, there are now several important factories for silicate bricks, vegetable oil, flour, salt, soap, cement, furniture, matches and textiles, as well as smaller enterprises. An important hydro-electric concession has been granted to Mr. Pinhas Rutenberg for the utilisation of the water powers of the upper waters of the Jordan and its tributary the Yarmuk. This work has not yet begun but power stations with oil engines have been erected at Tel-Aviv, Haifa and Tiberias, whereby light, power and heating are provided in these districts. Though Haifa seems likely to become the principal harbour, extensive improvements are contemplated at Jaffa, the centre of orange cultivation, and thus of more than half the total export trade of the country. The potash deposits of the Dead Sea constitute an important potential source of wealth. The balance of trade, shown below, is increasingly adverse, equilibrium being hitherto adjusted by immigration, tourists and charity.

|      | Imports   | Exports   |
|------|-----------|-----------|
| 1922 | 5,471,667 | 1,070,171 |
| 1923 | 4,825,185 | 1,143,234 |
| 1924 | 5,266,349 | 1,281,212 |
| 1925 | 7,338,491 | 1,297,559 |

Limited Companies (103) have established themselves under the law of Palestine, and 52 foreign companies registered themselves locally. On the expiry of Sir Herbert Samuel's term of office (July 1 1925) Lord Plumer was appointed high commissioner.

**PALESTINE, OPERATIONS IN.**—The British campaigns of 1914–8 in Palestine, Egypt and Syria covered an extensive stretch of territory, from the Suez Canal to Aleppo, a distance by the land route of well over 500 miles. This land route, the oldest highway in the history of the civilised world, along which the tides of thought and trade and war have flowed between Asia and Africa since time immemorial, traverses a remarkable variety of soil and scenery: the inhospitable desert of Sinai; the fertile plains of Palestine, flanked by the high rocky citadel of the Judean hills; the deep trench of the Jordan valley; and, finally,

Egypt was likely to form part of the Turkish strategical programme, largely inspired from Berlin. Seizure of the canal would paralyse the most vital line of communication of the British Empire and seriously hamper the gathering of its armies. Even the threat must immobilise considerable numbers for passive defence. The dream of reasserting dominion over their former province of Egypt was an additional lure to the Turks.

*The Turkish Advance.*—Between the southern frontier of Palestine and the Suez Canal lay over 100 m. of almost waterless desert. It was crossed by three routes, of which the northern, near the coast, through Rafah, El 'Arish and Qatiya to El Qantara, was the easiest and best. The Turks made their main effort on the centre route, from El 'Auja by the Wadi Muksheib, which reaches the canal about Tussum, south of Ismailia; but they also

the Syrian plateau with those cities of ancient tale, Damascus and Aleppo.

The fighting was as diversified as the terrain; it comprised battles in the desert and in fertile country, combats in steep bleak hills and in a sweltering valley below sea level, periods of close-locked siege warfare and intervals of rapid movement. The story of the successive advances of the Egyptian Expeditionary Force (as the British Army in this theatre came to be called) and of the gradual extension of its objective—from the passive defence of the canal to the delivery of the *coup de grâce* to the Turkish Empire—falls conveniently under four main heads: the Suez Canal, Sinai, Palestine, Syria.

### I. THE PROBLEM OF THE SUEZ CANAL

When Turkey entered the World War on the side of the Central Powers at the beginning of Nov. 1914, it was obvious that an advance from southern Palestine against the Suez Canal and

sent smaller forces by the coast road and by the southern route, through Nekhl to Suez, the most difficult of the three. The Turkish commander in Syria, Jemal Pasha, directed the enterprise, but its real brain was his Bavarian chief of staff, Col. Kress von Kressenstein. In spite of the difficulties, a force of some 12,000 to 15,000 Turks was brought within striking distance of the canal by the first days of Feb. 1915.

The British were not unaware of the danger—though they underestimated the Turkish effort—and were ready. The line of defence, which was held mainly by Indian troops, lay on the western bank of the canal, leaving the canal itself as an obstacle between the defenders and the enemy. A territorial division (the 42nd) and some Australian and New Zealand troops, who were completing their training near Cairo, formed the reserve. Warships in the canal provided gun support and compensated for the scarcity of land artillery. On the night of Feb. 2–3 the Turks made their effort, reached the canal, and actually succeeded

in pushing three pontoons full of troops across it. These were all killed or captured. An attack next day had no better success, and the Turks withdrew, unmolested by any serious pursuit.

This first Turkish raid, though it failed, proved the desert passable to large bodies of troops and thus compelled the retention of considerable forces in Egypt for the protection of the canal. It also showed the unsuitability of the defence on the west bank, since this line could not prevent the attackers from reaching the canal and interfering with the passage of shipping. No change was made in the system of defence, however, till after Lord Kitchener's visit in Nov. 1915. For during the summer and autumn of 1915 the Gallipoli campaign was in full swing and absorbed the principal efforts of both Turk and Briton. The Senussi rising in the western desert, too, occupied the attention of the G.O.C. in Egypt, Gen. Sir John Maxwell. After the evacuation of Gallipoli at the end of 1915 and beginning of 1916 Egypt contained close on 400,000 British troops, reorganising and recuperating after that gallant but ill-starred adventure. For a short time there existed within Egypt three separate and independent commands, but in March 1916 all three were united under Sir Archibald Murray.

Meanwhile, early in 1916, a line was taken up in the desert, some 8 to 10 m. to the east of the canal. Many miles of entrenchments were dug and revetted in the shifting sand, metalled roads constructed and pipe lines laid. For the Turk, freed from concern for the safety of his capital, was obviously contemplating a fresh advance on Egypt and the canal. He had in fact been busy with preparations ever since the repulse of his first effort.

This system of entrenchments, extending for some 80 m. along practically the whole length of the canal, was expensive in men as well as in material. This fact originated the first advance of the Egyptian Expeditionary Force and led to the crossing of the Sinai desert, an achievement made possible by sound and thorough organisation, and by the fine quality of the mounted troops, mainly Australians and New Zealanders, which the desert warfare developed and proved.

## II. THE SINAI DESERT

Sir Archibald Murray's objective was to secure control of the Sinai desert, which he saw could be effected by an advance to El 'Arish near the Egyptian frontier. A position here would bar the northern route across the desert and flank the more southerly routes. It would also enable offensive operations to be undertaken against enemy forces concentrating in southern Palestine. But an invasion of Palestine was not seriously contemplated at this time; the advance was initiated to safeguard Egypt and the Suez Canal. Murray estimated the force necessary at five divisions and four mounted brigades, a much smaller force than that needed adequately to garrison the defensive system along the canal. Moreover, the farther the defence was removed from Egypt the less chance there was of a sympathetic rising there on the approach of the Turk.

*British Advance on El 'Arish.*—The first step was to occupy the Qatiya oasis, 25 m. east of the canal, and thus deny to the enemy the only district within striking distance where a sufficiency of water permitted the assembly of a large force. The construction of a broad gauge railway from El Qantara towards Qatiya was begun, and large numbers of camels were collected to form the transport of the force, since in the soft sand of the desert wheeled transport was impossible. For the guns, special "pedrails" were constructed and teams doubled. Towards the end of April 1916, the Turks made a raid on the Qatiya oasis and surprised and captured some advanced posts of yeomanry. The Anzac Mounted Div., formed in March from Australian and New Zealand troops, reoccupied the area next day. The object of the Turkish raid seems to have been to cause alarm and thus to prevent the further withdrawal of troops from Egypt for France, which had been going on during the spring of 1916.

By July the advance had reached Romani at the western end of a scattered group of oases extending for some 15 to 20 m., when a strong Turkish force entered the eastern end. This force consisted of the 3rd Div. and certain other units, totalling about

18,000 men under Kress von Kressenstein. After a pause for preparation, at dawn on Aug. 4 it attacked the British position at Romani, held by the 52nd and 42nd Divs., the Anzac Mounted Div. and some yeomanry, in all about 30,000 men, under Lt.-Gen. the Hon. H. A. Lawrence. The Turks made a determined assault but were heavily repulsed and pursued as far as Bir el Abd. Their losses, including some 4,000 prisoners, amounted to nearly half their total force. They may perhaps be accounted fortunate to have escaped at all, for intense heat and lack of water precluded the more vigorous action in pursuit, which might have made possible the annihilation of the Turkish force.

The defeated Turks retreated to El 'Arish, leaving a small detachment at Bir el Mazar till the middle of Sept., when it was dislodged by the Anzac Mounted Division. There was no further fighting till December. The progress of the British force (now under Lt.-Gen. Sir Charles Dobell) towards El 'Arish was governed by the rate (about 20 m. a month) at which the railway and its accompanying pipe-line could be laid. The water supply available in Sinai was too brackish for constant drinking by troops; even the railway locomotives could not use it for long without loss of efficiency. The Sweetwater Canal, which runs from the Nile at Cairo to the Suez Canal, was the source of the pipe-line supply; from large reservoirs and a great pumping station built at El Qantara it was forced through a 12-in. pipe to railhead. In 1917 this pipe-line was extended up to Gaza.

*Occupation of El 'Arish and Rafah.*—Early in Dec. the railhead was within 20 m. of El 'Arish. Elaborate water and transport arrangements were now made to enable the advanced guard of the British force to capture El 'Arish. This advanced guard was known as the Desert Column, and consisted at this time of the Anzac Mounted Div. and 42nd and 52nd Divs., under Lt.-Gen. Sir Philip Chetwode. Just as all was ready, however, the enemy hurriedly withdrew and El 'Arish was occupied without fighting on Dec. 20.

The nearest Turkish force (1,600 infantry with four guns) was located at Magdhaba, some 20 m. south of El 'Arish. A flying column under Gen. Chauvel, consisting of the Anzac Div. and Imperial Camel Corps, was at once dispatched against it. After a night march Chauvel attacked the Turks in an entrenched position at dawn on Dec. 23. By late afternoon, at a cost of under 150 casualties, he had accounted for practically the whole enemy force, capturing 1,300 prisoners and burying 100 dead.

The only Turkish force now remaining within the Egyptian frontier was a detachment of about 2,000 near Rafah, 25 m. east of El 'Arish. This was dealt with in a similar fashion by the mounted troops under Chetwode. After a night march, he surrounded the Turkish position at dawn on Jan. 9. Some hard fighting followed, for the Turks were in a strong position and put up a stout defence. It was not till close on dark that the position was assaulted. The entire Turkish force was accounted for, while the British casualties were under 500. These two brilliant actions cleared the Egyptian province of Sinai from enemy occupation. They were striking examples of the power of boldly handled mounted troops, a power the Turk was to experience very thoroughly before the end of the War. Murray had now obtained his original objective, since the possession of Rafah and El 'Arish secured the safety of the Suez Canal and Egypt.

Towards the end of 1916 he had, however, received instructions which imposed on him a more active rôle than the mere defence of Egypt. While this defence was still to be the main consideration, it was made clear to him that the War Cabinet expected some more spectacular result of the "Exodus" across the desert than the negative one of giving checkmate to Turkish designs on Egypt. At the same time they were not prepared to give Murray the additional troops he asked for. Indeed, one of his four divisions, the 42nd, was early in 1917 withdrawn to France, leaving him only three in place of the five which he held to be the minimum to fulfil the rôle demanded of him. He had the nucleus of a fourth division—the 74th—to be formed from dismounted yeomanry; and the liquidation of the western desert campaign enabled him to add a second mounted division to the force on the Palestine border.

The situation in the early spring of 1917 was this: railhead was close to the Egyptian frontier at Rafa, some 20 m. from Gaza; the British War Cabinet's policy for the Egyptian theatre had finally crystallised into instructions to Sir Archibald Murray to prepare during the summer for an offensive campaign into Palestine in the autumn; and the Turk—now definitely on the defensive—had suddenly evacuated a forward position which he had prepared at Shellal, and had sketched out a position for the defence of Palestine between Gaza and Beersheba.

*The Palestine Offensive.*—Gaza and Beersheba, some 25 m. apart, are the two natural gates into Palestine from the south, the former by reason of its commanding position on the coast road, the latter as the last water base on the confines of the mountainous desert to east and south. Between Gaza and Beersheba, in an almost direct line, run a series of ridges which form a natural defensive position. Murray saw that in order to carry out his instructions to prepare for an autumn offensive, it was desirable to push his railhead forward out of the desert up to the cultivated plain of south Palestine. The conditions of transport would then be entirely different and camels could be largely replaced by wheeled transport. Moreover, the capture of Gaza would make it impossible for the Turk to hold the Gaza-Beersheba line as his main defensive position.

It was decided therefore in March to attempt the capture of Gaza by a *coup de main* similar to those at Rafa and Magdhaba, but on a much larger scale. The difficulties of concentration, of supply and of secrecy were of course much increased by the necessity to employ infantry in addition to mounted troops. The Turks had at the time some 7,000 fighting troops in Gaza, another 7,000 at Tel esh Sheri'a, half-way between Gaza and Beersheba, and a small garrison in Beersheba.

The plan was, briefly, for the mounted troops to pass east of Gaza, cut the garrison's line of retreat, and hold off the arrival of any Turkish reinforcements from the north or east. The 53rd Div. was to assault the heights east and south of Gaza, while the 54th Div. protected the exposed right flank from the direction of Tel esh Sheri'a.

*Attacks on Gaza.*—The enterprise took place on March 26. Unfortunately, a dense sea fog came up with the dawn and caused a delay of two precious hours in the deployment of the infantry. This delay, which could not have been foreseen nor prevented, was the direct cause of the loss of the battle. For the Turkish position was strong, and it was not till 5 P.M. that the 53rd Div. secured the 'Ali el Muntar ridge which dominates Gaza from the east; at the same time, a part of the mounted troops were in the northeastern outskirts of the town. The victory was to all appearances won. In fact the garrison, as was afterwards known, was on the point of surrender. But Turkish reinforcements from the north and east were already pressing on the protective screen of the mounted troops; the horses were without water, and darkness was coming on. It had been agreed beforehand that the enterprise should be abandoned if Gaza had not fallen by dark. The reports received did not indicate a successful issue; owing to a breakdown of communications, news of the success of the 53rd Div. did not reach the British commander till about 11 P.M. Sir Charles Dobell hesitated to involve his infantry in the intricate network of cactus hedges which surrounds Gaza, while Chetwode was against exposing his mounted troops, exhausted by want of water, to the danger of being overwhelmed by the approaching Turkish reinforcements. The withdrawal of the mounted troops was ordered. This exposed the right of the 53rd Div., which had to be drawn back from the 'Ali el Muntar heights to gain touch with the left of the 54th. The battle was resumed next morning, but the Turkish garrison had been reinforced and had taken heart of grace at the unexpected respite of the previous evening. It was found impossible again to make good the 'Ali el Muntar ridge, the key to Gaza; and finally the whole force was withdrawn to the Wadi Ghazze.

This first battle of Gaza has been a matter of dispute and conjecture. By many of the troops who took part, it was held that the decision to withdraw threw away a victory already won. On the other hand, it is impossible to question that in the cir-

cumstances the order for retirement was justified. The two-hour delay in the morning lost the battle. Other contributory causes were the breakdown of communications (partly due to shortness of equipment) and lack of accurate maps, which made it impossible for H.Q. to obtain timely information of the progress of the fight.

Though the enterprise had failed, the force had secured a position on the Wadi Ghazze which would enable railhead to be advanced to within a short distance of Gaza in preparation for the autumn campaign. Murray now, however, received instructions to commence an offensive movement at once. A fresh assault on Gaza was therefore prepared. But the conditions were now very different; the Turk had closed the gap between Gaza and Beersheba by a series of works, and had greatly extended and strengthened the defences of Gaza. He had some five divisions in line and a considerable quantity of heavy artillery, so that Gen. Dobell's force had no easy task. Much hope was placed in some tanks, which were to be used in Eastern warfare for the first time. The attack was made in two stages, of which the first, on April 17 was designed to gain a position from which the final thrust on Gaza could be made. It was successful. But the decisive attack on April 19 failed with heavy loss; the tanks developed mechanical defects in the heavy sand or were put out of action by the well-placed Turkish guns; and the weight of artillery supporting the British attack was insufficient to demolish the formidable defences of Gaza. The British casualties were 7,000.

Operations before Gaza now settled into regular trench warfare. The Sinai campaign was at an end. It had fulfilled its object, the security of Egypt; and the careful and thorough organisation which had conquered the desert had laid a solid foundation for the future British successes. For this Sir Archibald Murray deserves the greatest credit. He had never been given the number of troops which he had repeatedly stated was the minimum necessary for more extended successes.

### III. PALESTINE

A long pause in active operations followed the second battle of Gaza. The Turks, under German leadership, were now gathering their last resources at Aleppo for an attempt to recapture Baghdad. They christened this force the "Yilderim" ("lightning") group. The British General Staff decided to forestall this enterprise by an attack in Palestine which would divert this army southwards from Aleppo and remove the danger to Baghdad. The British Government also no doubt hoped by a spectacular success in the East to remove some of the disappointment caused to the public by the failure of Nivelle's offensive in France and the military collapse of Russia. Gen. Sir Edmund Allenby succeeded Sir Archibald Murray in July, 1917, with instructions to report on the conditions in which offensive operations could be undertaken against the Turkish forces on the Palestine front.

*Allenby's Plan Outlined.*—Allenby based his plan on an appreciation made some time previously by Lt.-Gen. Sir Philip Chetwode, who now commanded on the Gaza front. The obvious line of advance was by Gaza, which would allow of naval co-operation, directly cover the lines of communication, and present comparatively small difficulties of water supply. But the defences of Gaza were too solid to be broken except by a slow and costly process of siege. The Turkish centre was also strong and the approach to it difficult. There remained the Turkish left, which rested about Abu Hureira, some 7 m. west of Beersheba; the defences here were weaker and less complete, and might perhaps be rapidly overwhelmed. This would provide an opportunity for the mounted troops, the arm in which lay the chief superiority of the British force over the Turkish.

A preliminary operation was necessary to capture Beersheba, which the Turks held by a detached force; for there was not room to manoeuvre between Beersheba and the Turkish left; moreover possession of the water supply at Beersheba was essential to further operations. The difficulties of capturing Beersheba and of placing a sufficient force within striking distance of the Turkish left were, however, serious. The three principal problems to be

solved were those of transport, water supply and secrecy. Until the Gaza-Beersheba line had been passed and the cultivated plain of Palestine reached, it was not practicable to use motor lorries, and the force was dependent on horsed transport and camels. This limitation greatly increased the difficulties of water supply, which was the second main problem. Its seriousness is illustrated by the fact that the striking force estimated as necessary for operations against the Turkish left required some 400,000 gallons of water daily. Of the 30,000 camels available the majority would be required to carry water. The third great difficulty was to concentrate a striking force sufficient to overwhelm the garrison of Beersheba rapidly and then attack the Turkish left, without the Turks becoming aware of the plan and taking steps to counter or avoid the blow.

In spite of the difficulties to be overcome, Gen. Allenby decided to attack the Turkish left. He estimated the total force required at seven divisions and three mounted divisions with additional artillery and aeroplanes. Four divisions and two mounted divisions were to attack the Turkish left, three divisions were to make a subsidiary attack on Gaza, and one mounted division was to watch the centre between these two wings, which would be separated by some 20 m. during the operations.

The number of divisions was made up to the required total by the 10th and 60th from Salonika and by the completion of the 75th, already in process of formation. Allenby formed his three mounted divisions into the Desert Mounted Corps, under Lt.-Gen. Sir H. Chauvel, an Australian, and his seven divisions into two Corps, the XX., under Lt.-Gen. Sir Philip Chetwode, and the XXI., under Lt.-Gen. Sir E. Bulfin. The elaborate preparations necessitated by the character of the forthcoming operations occupied the summer and early autumn. The railway across the desert was doubled; and arrangements were made for its rapid extension during operations; ammunition and other stores were accumulated; and the troops underwent special and intensive training. The development of the water supply was also a constant preoccupation.

Meanwhile, Gen. von Falkenhayn, in command of the Turkish Army at Aleppo, had realised that the security of the Palestine front was essential to the successful prosecution of the plan for the recapture of Baghdad. It was accordingly decided to drive the British back into the Sinai desert before committing the Yıldırım force to the Mesopotamian adventure. All troops available at Aleppo (only three divisions) were ordered to south Palestine during September.

Both Turks and British were thus aiming to strike a blow on the Palestine front in the autumn of 1917, and each hoped to forestall the other. The poverty of the Turkish lines of communication decided this issue by the delay it imposed on the southward movements of men and stores. From Haidar Pasha, the Turkish main base on the Asiatic shore of the Bosphorus, to railroad in Palestine was a distance of 1,275 m., with a single line of rail only, which, up to Aleppo, had also to serve the Mesopotamian front. The incomplete tunnels in the Taurus and the differences in gauge of the various lines necessitated five or six transshipments of all stores before they reached Palestine. Scarcity of fuel and jealousies between the German commanders and staff and the Turkish officials who controlled the working of the communications further accentuated the difficulties. Consequently, the supply problem crippled Turkish movements throughout these campaigns. The force from Aleppo was still in process of arrival on the Palestine front when Allenby struck his blow.

*Disposition of the Troops.*—During the days previous to Oct. 31, the date fixed by Allenby for the attack on Beersheba, the Desert Mounted Corps and the XX. Corps (10th, 53rd, 60th, 74th Divs.) were gradually and secretly moved across to the right wing from behind Gaza, where they had been in training camps by the sea. There could be no question of concealing entirely the preparations for a movement against Beersheba; but Allenby did hope to persuade the Turks that this movement was only a feint and that the real main attack was against Gaza. To this end the XXI. Corps (52nd, 54th and 75th Divs.), left opposite Gaza, began on Oct. 26 a heavy bombardment of the

Turkish defences, assisted by British and French warships from the sea. The intended deception as to the real point of attack was aided by the natural nervousness of the Turk of operations by sea against his right flank. He was also perfectly aware of the great difficulties of transport and water supply in the country opposite his left flank, which he believed was sufficiently safeguarded by these natural obstacles.

The Turkish forces at the end of Oct. consisted of the VIII. Army (six divisions) under Kress von Kressenstein, holding Gaza and the Turkish centre, and the VII. Army (three divisions), holding Beersheba and the Turkish left. The VII. Army was not yet complete, one of the divisions from Aleppo being still on the lines of communication. Von Falkenhayn, who was to combine the action of these two armies, only arrived at Jerusalem on Nov. 1. The approximate fighting strengths of the Turkish and British forces were: Turks, 50,000 rifles, 1,500 sabres, 300 guns; British, 95,000 rifles, 20,000 sabres, 300 guns.

Allenby's plan for Oct. 31 was as follows: Two divisions of the XX. Corps, the 60th and 74th, were to attack the southwestern defences of Beersheba, which lay some 4 m. from the town itself, with the 53rd Div. protecting the left flank of this attack. The Anzac and Australian Mounted Divs., which had concentrated at El Khelasa and Bir 'Aslūj, were to reach a position east of Beersheba by dawn, close the Beersheba-Hebron road, and then attack and carry the town as rapidly as possible, before the Turks could destroy the wells.

*Capture of Beersheba.*—During the night of Oct. 30-31 the assaulting infantry and artillery moved some 8 m. to their positions of deployment, while the mounted troops undertook a ride of over 25 m. to reach a position east of Beersheba. These long and complicated night movements were only made possible by careful preparation and good staff work. At dawn on Oct. 31 the attack of the XX. Corps commenced. A Turkish forward work, Hill 1030, had to be taken, to allow the artillery to get within wire-cutting range of the main position. Hill 1030 was taken at 8:30 A.M.; the main assault was delivered at 12:15 P.M. and was successful; by early afternoon the British infantry were masters of the Turkish defences southwest of the town; they were still, however, some miles from the town itself. Meanwhile, the mounted troops, after closing the Hebron road, had been held up by a Turkish strong point at Tel es Saba, 3 m. east of Beersheba. When this was at last taken, little time remained if the town was to be captured before dark. Gen. Chauvel accordingly ordered a mounted attack at 4 P.M. The 12th Australian Light Horse Bde. charged over the Turkish trenches and rode straight into the town. This daring and well-executed charge resulted in the capture of over 1,100 prisoners and 10 guns, and saved the all-important wells from demolition. The infantry had captured another 900 prisoners, and the Turkish 27th Div. had suffered practical annihilation. While the preparations for the decisive attack on the Turkish left were being made, the XXI. Corps carried out a holding attack at Gaza on the night of Nov. 1-2. A considerable portion of the Gaza defences was carried and heavy losses caused to the Turks.

Left to themselves, the Turkish commanders would now probably have retired to a fresh position while there was yet time. But Von Falkenhayn, imbued with German principles of defence and ignorant of the qualities of the Turkish troops he led, ordered a counter-attack with all available reserves to the north of Beersheba. This led to three days' heavy fighting against the British 53rd Div., which had been sent into the hills to guard the right flank of the XX. Corps. The 53rd Div. held its own; consequently, when at dawn on Nov. 6 the remainder of the XX. Corps (10th, 60th and 74th Divs.) attacked and broke through at Abu Hureira, the Turks had no reserves to restore the situation. By nightfall Gaza was being evacuated and the whole Turkish force was in full retreat.

The pursuit by Allenby's mounted troops was hampered by lack of water; and the Turkish rear-guards were well handled. A gallant charge at Huj on Nov. 8 by some squadrons of Worcestershire and Warwickshire Yeomanry captured three batteries of guns; but no large bodies of Turks were cut off; and the supply

question limited the number of divisions which could be used in the pursuit.

On Nov. 11 the Turks took up a position to cover Junction Station, where the railway to Jerusalem branches off the main line. After a short pause to organise for attack, Allenby's pursuing troops attacked on Nov. 13 and soon dislodged their enemy; in an action remarkable mainly for a dashing charge by a brigade of yeomanry on a strongly held hill above the village of El Mughaiyir. On the following day Junction Station was captured; Jaffa was occupied on the 16th. The capture of Junction Station definitely divided the Turkish armies; the VII. was left in the hills to defend Jerusalem, while the VIII. was in the plain to the north of Jaffa; there was no good communication between the two armies south of the line Tul Karm-Nablus.

*Before Jerusalem.*—Allenby had originally intended to wait until the development of his communications allowed of his whole force being brought up before turning into the difficult hills towards Jerusalem. He now decided to oppose the Turkish VIII. Army with a detachment, while with the remainder of his force he turned east and advanced on Jerusalem at once. It was a bold decision, since he had only three infantry and two mounted divisions immediately available, and the supply of these strained the resources of his transport to the utmost; the troops available had already done much hard marching and fighting; little was known of the hill country save that it was very difficult and that there was only one road fit for wheels. The Anzac Mounted Div. and the 54th Div. were left to hold the Turkish VIII. Army in the plain, while the remaining three divisions advanced into the hills, the 75th up the main road, the 52nd on its left and the Yeomanry Mounted Div. on the left of the 52nd. Both these two latter divisions were entirely dependent on pack transport. The intention was to pivot on the 75th, when that division arrived within a certain distance of Jerusalem, and to swing the left across the Jerusalem-Nablus road north of the city. It was hoped thus to compel the surrender or withdrawal of the defending Turks and to avoid fighting in the close vicinity of the Holy City.

There was some hard fighting on Nov. 20 and 21; the 75th Div. captured the crest of the ridge at Enab in a fog on Nov. 20 and on the 21st stormed the commanding hill of En Nabi Samweil; the 52nd made similar progress; and the yeomanry were at one time within a short distance of the Nablus road. But the British effort had shot its bolt; the men were suffering much from cold and wet, and the artillery support available was insufficient against strong prepared positions. The yeomanry were counter-attacked and driven back, and the 52nd and 75th could make no headway; by Nov. 24 it was evident that without fresh troops and a period of preparation Jerusalem could not be taken. The difficult passes through the hills had, however, been secured and the boldness of the advance justified.

A pause now took place while the British Army improved its communications and thus enabled the XX. Corps to be brought up from Gaza, where it had been left for convenience of supply. It took over the line opposite Jerusalem, releasing the troops which had made the first attempt to strengthen the line in the plain. Von Falkenhayn during this period ordered small local counter-attacks all along the line in the hope of disorganising Allenby's plans. But these attacks had no effect and merely wasted the best remaining elements of the Turkish force.

The second attack on Jerusalem was delivered at dawn on Dec. 8, in mist and rain. The brunt of the fighting fell on the 60th (London) Div., assisted on the left by the 74th Div. and on the right by the 53rd Div., which had previously moved up from Beersheba along the Hebron road to within striking distance. By the evening the Turks had decided to withdraw, and the city surrendered next morning. Allenby made an official entry on Dec. 11. His brilliant campaign effectively removed all danger to Baghdad from the Yildirim Army, the whole of which had of necessity been used in Palestine. The last reserves of Turkish man-power were practically exhausted; and Turkey was now in a far worse plight than when Germany had, at the commencement of 1917, undertaken the re-establishment of her military

prestige by driving the British out of Baghdad. Von Falkenhayn had completely failed to grasp either the conditions of the theatre or the idiosyncrasies of Turkish troops. He was replaced early in 1918 by Liman von Sanders.

*Rising of the Arabs.*—The encouragement given by the British success to the Arab revolt caused an additional drain on Turkish resources. The Arab revolt had broken out a year previously, when Hussein, the Sherif of Mecca, induced the Hejaz to rise against the Turk. Jeddah and Mecca were soon captured, but the Medina garrison held out. The revolt would probably have ended in the re-establishment of the Turks, or in desultory warfare with little result, had there not appeared a young Englishman with an understanding of the Arabs and a gift for guerrilla tactics. As Col. Lawrence he became famous. He persuaded Feisal, a son of Hussein, who led the Arab forces in the field, that the true policy lay not in assaults on the Turkish garrison in Medina, which if successful would merely rid the Turks of an embarrassment, but in gradually spreading the revolt northward up to the very gates of Damascus, with propaganda as the principal weapon, and in ceaseless raiding on the long exposed Turkish communications to Medina, which would form a constant drain on the enemy's resources.

In pursuance of this policy, Feisal, with Lawrence as his adviser, moved his base of operations from opposite Medina, first to Wejh and next to Akaba, which Lawrence had captured by a dashing raid. Gen. Allenby was quick to realise the service which the Arab rising was rendering to his operations, and was always sympathetic to Lawrence's requests for equipment or other aid in kind.

Allenby's next aim was obviously to secure sufficient room for manoeuvre in front of Jerusalem in the hills and Jaffa in the plain. On Dec. 20 and 21 the 52nd Div. forced a passage of the river El 'Auja, and drove the Turks 8 m. north of Jaffa, thus improving the position in the plain. In the hills, all preparations had been made for an operation to drive the Turks farther from Jerusalem, when information was received that the Turks themselves were about to attack. Reinforcements, including the 1st Div., had reached them, and Von Falkenhayn was determined on an attempt to recapture the Holy City. The attack was pressed with great gallantry on Dec. 26, but made no impression; on the following days the counter-attack of the British XX. Corps carried them some 5 or 6 m. forward and safeguarded Jerusalem from the north. Later, the eastern flank was secured by the capture of Jericho, which took place on Feb. 21. Early in March, the line was pushed still farther north, both in the hills and in the plain, by a series of small operations. Thus by the spring a strong line had been secured, which might have been held by a reduced force in the exhausted state of the Turks.

*Plans for 1918.*—Meanwhile, the future of the Palestine campaign in the general plan of the Allies for 1918 had become the subject of considerable discussion. In view of the expected great German offensive in the West, there was a considerable body of opinion amongst those who directed the Allied strategy in favour of closing down as far as possible all commitments in minor theatres and of concentrating on the vital Western Front all reinforcements that could be spared from them. It was also pointed out that the maintenance of large forces on the Palestine front entailed heavy losses in shipping—which was likely to prove the Achilles' heel of the Allies—since the submarine menace was especially serious in the Mediterranean.

On the other hand, it was believed by many that neither side could force an issue on the Western Front, so formidably entrenched, and that the War could be won by the elimination of Germany's weaker Allies. They held that one more blow would force exhausted Turkey to sue for peace; and consequently advocated a further offensive in Palestine. This policy was eventually adopted. Two divisions, the 3rd and 7th Indian, were moved from Mesopotamia to reinforce Allenby's army, and all preparations for a fresh great offensive were being made, when the storm broke on the Western Front. The success of the German offensive of March 21 caused a demand on Allenby for all the troops he could spare, which of course necessitated the post-

ponement of his operations. During April and May, two complete divisions (the 52nd and 74th), 24 additional British battalions, nine regiments of yeomanry and five and a half heavy batteries were withdrawn from the Egyptian Expeditionary Force and dispatched to France. These were gradually replaced by Indian cavalry from France and Indian units from India, and the Egyptian Expeditionary Force was reorganised on an Indian basis. It required much training and organisation to weld all these new, and in some cases raw, units into an effective whole; but by the end of the summer the Egyptian Expeditionary Force was again ready to strike a decisive blow.

*Preliminary Operations in 1918.*—Meanwhile, in March and May, Allenby had carried out two raids to the east of the Jordan. These raids were an important part of his strategical plan. He had decided that his next great advance should be initiated from his left flank along the coastal plain, where his great superiority in the mounted army could be exploited. Therefore, the more of the Turkish Army he could draw over to the opposite flank, east of the Jordan, the easier would it be to break through on the coast when the time came. The railway junction at Deraa was a vital point in the Turkish communications. If the Turkish Command could be persuaded by demonstrations east of the Jordan that a move in force up the Hejaz railway was a possibility, and if Feisal's Arabs could be encouraged to attack Deraa and the railway where it ran down the Yarmuk valley, the Turks would be obliged to move troops east of the Jordan. With these objects the raids east of the Jordan were undertaken. Neither was a complete tactical success. The first raid reached the railway near Amman and cut it in several places, but failed to capture Amman before supply difficulties caused by vile weather necessitated its withdrawal. In the second raid, the mounted troops reached Es Salt; but the Turks could not be driven from their strong positions in the Shunet Nimrin pass; and the defeat of the left flank guard of the mounted troops, with the loss of nine guns, rendered their position at Es Salt dangerous and compelled a withdrawal.

But the two raids had the desired effect of seriously alarming the Turks for their left flank. After the second, Liman von Sanders, who was now in command, had been induced to place one-third of his total force east of the Jordan, with a corresponding weakening of his forces west of the Jordan. Allenby kept alive the opposing commander's fears for this flank by maintaining throughout the summer, in spite of the heat, a considerable force in the valley of the Jordan. In July the German units operating with the Turks made an abortive attack on part of the position of the Desert Mounted Corps. Elsewhere on the front there was little serious fighting during the summer.

#### IV. SYRIA

At the end of the summer of 1918 the Turkish forces were distributed as follows, on a front of 65 m.: the VIII. Army (five divisions and three German battalions), in the coastal plain and the foothills, faced the British XXI. Corps; the VII. Army (four divisions), in the Judean hills astride the Nablus road, faced the British XX. Corps; while the IV. Army (two divisions, one cavalry division and one composite division), in the Jordan valley and east of the Jordan, was opposed to the Desert Mounted Corps. The total fighting strength of the Turks amounted to 32,000 rifles, 3,500 sabres, 350 guns; and that of the British to 57,000 rifles, 12,000 sabres, 540 guns.

Gen. Allenby's plan was the reverse of that of the Gaza-Beersheba battle; then, he had struck the Turkish left while persuading them that his real effort was to be made along the coast against their right; now, he proposed to advance along the coast, while deceiving the Turks into thinking that their left flank was threatened. Steps were skilfully taken to simulate a concentration of troops in the Jordan valley, whereas in fact only a skeleton force, the Anzac Mounted Div. and a few battalions, was left there. The real concentration was being secretly made in the coastal plain, to which the bulk of the Desert Mounted Corps and the 60th Div. of the XX. Corps were transferred. For the success with which this concentration was con-

cealed from the Turks to the last, British superiority in the air was largely responsible.

A simple statement in figures shows how well Allenby had succeeded in obtaining an overwhelming superiority of force at the decisive point. When his concentration was complete, he had on a 15-m. front in the coastal plain 35,000 infantry and 400 guns against only 8,000 Turks with 130 guns; and behind this mass of infantry were three cavalry divisions waiting to exploit success. On the remaining 45 m. of front he left only 22,000 infantry with 150 guns, facing 24,000 Turks with 270 guns. And the Turks were still unaware of his intentions or of the distribution of his force.

*The September Offensive.*—The attack was made at 4:30 A.M. on Sept. 19. The preliminary bombardment lasted only 15 min., and the infantry assault, pushed at great speed and in overwhelming strength on a broad front, was rapidly successful. By 7:30 A.M. the leading cavalry division was through the enemy's lines. The orders to the mounted troops were to ride straight north,

disregarding any hostile troops that did not directly bar their path, cross by the passes near Megiddo into the Plain of Esdraelon, and secure El Afule and Beisan to block the Turkish lines of retreat.

The leading troops of the 5th Indian Cav. Div. reached Nazareth, Liman von Sanders' headquarters, just 24 hours after their start, having covered 52 m.; they failed only by accident to capture the person of the enemy commander-in-chief. The 4th Cav. Div., moving farther to the east, covered 70 m. to Beisan in 34 hours. The advance was carried out with great dash and there were several instances of successful mounted attacks. A regiment of the 5th Cav. Div. rode over a Turkish battalion in the Plain of Esdraelon; and a brigade of the Australian Mounted Div. galloped into the village of Jenin, occupied by a numerous force of Turks and Germans, thus sealing one of the main exits from the trap in which the Turkish VII. and VIII. Armies were now caught. Meanwhile the British infantry of the XXI. Corps, after breaking through the Turkish fortified system in the plain, had wheeled to the right and driven the remnants of the Turkish VIII. Army into the hills. The 60th London Div. (Maj.-Gen. Shea) actually reached Tulkeram before dark on the 19th, having fought and marched 18 m. over very heavy going.

During the two days following Sept. 19 the XXI. Corps continued to press their pursuit, while the XX. Corps also pushed forward along the Judean hills to Nablus. The infantry of these two corps thus shepherd the straggling remains of the Turkish VII. and VIII. Armies into the hands of the mounted troops. The Royal Air Force, with bombs and machine-gun fire, caused havoc amongst the bewildered Turkish transport, penned in and crowded on narrow hill roads. Only a few of the most determined Turks and some of the better fed and disciplined German units managed to break out to the east and cross the Jordan. The Germans fought well throughout the retreat.

Meanwhile, the Turkish IV. Army had remained inactive, ignorant of the fate of the other armies. On the 22nd it began a hurried retreat on Amman, hoping thence to escape up the Hejaz

railway to Damascus. It paused at Amman till Sept. 25, awaiting the arrival of the Maan garrison from the south. But the IV. Army was now not only too late to rescue this force, but too late to secure its own safety. Feisal's Northern Arab Army was already between it and Damascus, and the whole countryside was rising against the Turks. The Arabs under Lawrence had already contributed largely to the discomfiture of the Turks by their raids on the lines of communication near Deraa, which they cut effectively from Sept. 17 onwards. They were now in a position to delay and harass the IV. Army in its march north.

*The Final Victory.*—The Turkish VII. and VIII. Armies having been disposed of, Allenby ordered a part of his mounted troops to occupy Haifa, which was captured Sept. 23 by a most gallant charge of the Indian Imperial Service Brigade. The remainder were dispatched east and northeast to cut off the IV. Army and to capture Damascus. The 4th Cav. Div. was to cross the Jordan near Beisan and move on Deraa, while the Australian Mounted Div. was to make direct for Damascus by the road which runs from Nazareth to the west of Lake Tiberias, crossing the Jordan at Jisr Benat Yakub. On Sept. 25 there was a fierce fight at Tell es Semakh at the southern end of Lake Tiberias. The 4th Australian Light Horse Bde. charged in the dark over unknown ground and captured the village after hand-to-hand fighting with a force composed largely of Germans.

The Turkish IV. Army passed Deraa before the 4th Cav. Div. could head it off, but under pressure from this division and from the Arabs it gradually disintegrated. The end came on Sept. 30, when the Australian Mounted Div., which on Sept. 28 had overcome some determined opposition to its crossing of the Jordan, succeeded in getting astride the Damascus-Beirut road just outside the city, cutting off the remains of the IV. Army. Damascus was occupied next day, Oct. 1. Immediately after the capture of Damascus, malaria and influenza broke out and placed a great proportion of the British mounted forces out of action. It also seriously affected the very numerous Turkish prisoners.

There was now no formidable Turkish force in southern Syria. To complete its occupation, two columns advanced. The 7th Div. left Haifa on Oct. 1 and moved up the coast to Beirut, which it reached on the 8th, and then on to Tripoli, which was occupied on the 18th; the 5th Cav. Div., which though less affected by malaria and influenza than other formations, was considerably below establishment, advanced from Damascus by Homs (Oct. 16), Hama (Oct. 20) to Aleppo, which was occupied on Oct. 26. The last fighting took place north of the town on the 28th. On the 31st an armistice was concluded. Between Sept. 19 and Oct. 26 the British Army had moved its front forward a distance of 360 miles. During this period the 5th Cav. Div. had actually covered over 500 miles. The captures included 72,000 Turks and nearly 4,000 Germans and Austrians, 350 guns, 800 machine guns and large quantities of transport and other material. History records few victories, if any, more striking and complete.

*Conclusions.*—These campaigns of the Egyptian Expeditionary Force are of great strategical interest. For the military student they will always remain classic examples of the use of mounted troops and of the value of mobility. Conditions of war change, and it may be that some mechanical form of transport will entirely replace the horse as the means by which mobility can be secured. But the power of mobility as a strategical weapon, in the hands of a commander who has the knowledge and the determination to use it as did Gen. Allenby, will only be enhanced. A second strategical lesson is the advantage gained by a commander who can conceal his intentions from his opponent. In both his great battles against the Turk, Allenby completely deceived his adversary as to his plans, and had thus secured a decisive superiority before the battle was joined. Only constant foresight and careful preparation can effect this. Air superiority is a factor of increasing importance in this question of concealment of plans and movements.

Finally, the dependence of all strategy on the communications may be stressed. The Turks added to the initial handicap which their long and difficult lines of communication imposed on them by their neglect to improve these and by the inefficiency of their

working. Von Falkenhayn, during his command, entirely failed to adapt his strategy to the limitations necessitated by his means of transport. On the British side, the greatest care was devoted to developing the communications in accordance with the strategical plan, and the supply services were thus able to cope even with such problems as were presented by the rapidity of the advance to Damascus and Aleppo.

**PALGRAVE, SIR ROBERT HARRY INGLIS** (1827-1919), British banker and economist, was born at Westminster June 11, 1827, the son of Sir Francis Palgrave, the historian (see 20.620). He was educated at Charterhouse and entered Barclay's Bank at Yarmouth. There he rose to a position of such importance that in 1875 he was one of three representatives of the English issuing country bankers chosen to give evidence before the select committee of the House of Commons on Banks of Issue. He edited *The Economist* from 1877 to 1883, and published many works on banking, as well as *The Local Taxation of Great Britain and Ireland* (1871). He also edited *The Dictionary of Political Economy* (1894-1906). He was knighted in 1909, and died at Bournemouth Jan. 25 1919.

**PALM BEACH, Fla., U.S.A.** (see 20.643), one of the most luxurious of the winter resorts on the east coast (population, 1920, 3,135). Opposite to it is West Palm Beach, which stretches for eight miles along Lake Worth, and advertises itself as the place "where summer spends the winter." Its population in 1910 was 1,743; in 1920, 8,659; and in 1925, according to the state census, it was 19,146. Both shared in the Florida boom that began in 1922. An extension of the Seaboard Air Line in 1924 established rail connection with the west coast, and more than 2,000 houses were built in the next 12 months.

**PANAMA** (see 60.664).—A republic of Central America, situated between Colombia and Costa Rica. It has an area of 32,380 square miles. The Panama Canal has been cut across the narrowest part from Colón to Panama, and the area, except for the towns of Panama and Colón, is for five miles on each side of the canal under the control of the United States. Panama declared war on Germany on April 7, 1917, and acquired membership in the League of Nations in 1920. The inhabitants are of mixed race, the chief elements being Spanish, Indian and negro. The population according to the 1920 census was 446,098, excluding the 22,858 inhabitants of the Canal Zone. The population of Panama, the capital, in 1920 was 59,458; Colón, at the Atlantic entrance to the canal, had a population of 31,203.

#### POLITICAL HISTORY

The amended constitution of Dec. 26 1918 provided that the president should be elected by direct vote and should be ineligible to succeed himself. Provision was also made for three *designados* or vice-presidents, of whom the first would hold office as *ad interim* president in the event of the president dying whilst in office. In 1912 Belisario Porras was elected president for the term ending 1916. In the latter year the elections were held in disturbed civil and political conditions, and Ramón M. Valdéz was elected for the term 1916-20. Valdéz died in 1918, his term of office being completed by Ciro L. Orriola. Ernesto Lefevre was inaugurated Jan. 30 1920; but in Aug. Dr. Belisario Porras was elected to office, and inaugurated for a term of four years on Nov. 1. He was succeeded on Nov. 1 1924 by Rodolfo Chiari, who was elected for the term 1924-8. The dispute with Costa Rica over the demarcation of the boundary line between that country and Panama resulted in the United States Secretary of State notifying Panama that the White award of 1914 must be accepted (see COSTA RICA).

In 1922, on the recommendation of President Harding, the Hay-Bunau-Varilla Treaty of Feb. 23 1904 (see 20.670) was dis-

cussed at Washington for the purpose of removing causes of friction between Panama and the United States. The disputed matters were the property valuation of the Canal Zone, the establishment of a free port and arrangements for docking privileges. Panama contended that the United States had never acquired the zone in fee simple, and that the zone republic should exercise sovereign rights in fiscal jurisdiction therein. The United States contended that the treaty conferred upon its Government all such rights. Negotiations during 1923 and 1924 reached a partial deadlock in July of the latter year. Part of the trouble arose from the practice of the United States in leasing cold-storage plants and warehouses in the zone to private individuals. Panama claimed that this violated her sovereignty. It was finally agreed that the *status quo* should continue pending the negotiation of a new treaty. In Jan. 1926 no solution of the difficulties by new treaty provisions had been announced. In Oct. 1924 legislation was initiated, excluding near relatives of incumbents of the presidency from the succession and increasing the term of supreme court justices from four to 10 years. Panama has no army or navy, but maintains municipal and rural police. The police force of the zone is maintained by the United States and has no authority outside.

**Education.**—Primary education is compulsory for all children from seven to 15 years of age. In 1923 there were 43,215 children attending the 384 Government schools in the eight provinces of the republic, excluding the children attending the public schools of the Canal Zone. In 1911 the Instituto Nacional was established in Panama for university education. In 1923 there were 20 private educational establishments in the republic, as well as a training college for girls and a school of arts and crafts for boys.

**Finance.**—The Panama Govt. receives all the import duties collected, but the United States imports all canal material and supplies for Government use free of duty. Financial stabilisation began in 1920, when a fiscal agent, detailed from the Zone Q.M. Service, was placed in charge. The finances as reorganised are based on a triennial budget. A plan of long-term agricultural credits was arranged under amortised mortgages, whereby the registry of land titles was expedited. For 1922 expenditure was \$6,900,217 and revenue \$5,299,999; for 1923 expenditure was \$7,568,124 and revenue \$10,299,212, including a loan for \$4,500,000 floated in New York in 1923 for road construction.

**Production and Industry.**—The chief products of Panama are bananas, coconuts, hides, coffee, cacao and *tagua* (vegetable ivory). Only a small area of land is cultivated. The production of sugar has increased, and the cultivation of tobacco has been encouraged by the Government. Bananas were the chief export, amounting in value to more than half the annual exports. Pearl-fishing is carried on in the Gulf of Panama, and tortoiseshell is exported. All international commerce moves through Cristóbal and Balboa, Bocas del Toro being reserved for local business. Over 90% of the total exports go to the United States, which also dominates the import business.

Trade figures (excluding the Canal Zone) for the years 1921-4 were:—

|             | Imports      | Exports     |
|-------------|--------------|-------------|
| 1921        | \$11,372,370 | \$2,495,407 |
| 1922        | 10,268,548   | 2,487,478   |
| 1923        | 12,674,375   | 2,389,728   |
| 1924 (est.) | 13,000,000   | 3,250,000   |

The trade of Panama (including the Canal Zone) with the United States for the same period was as follows:—

|      | Imports      | Exports     |
|------|--------------|-------------|
| 1921 | \$23,144,000 | \$3,865,000 |
| 1922 | 14,517,000   | 3,697,000   |
| 1923 | 21,769,000   | 4,267,000   |
| 1924 | 26,366,000   | 5,904,000   |

The total trade of Panama with Great Britain for the same period was:—

|      | Imports  | Exports  |
|------|----------|----------|
| 1921 | £305,095 | £138,983 |
| 1922 | 218,450  | 65,544   |
| 1923 | 354,026  | 87,587   |
| 1924 | 414,378  | 105,257  |

Concessions have been granted to 10 commercial undertakings for the exploitation of oil lands in the republic, the last of the concessions having been granted in May 1924. Under the terms of the contract the concessionaire is required to pay to the Government the sum of 15 cents for each hectare conceded, with a stipulated preference of

developing for a term of 30 years should oil be struck. Only three companies had carried out boring operations in 1924. Panama has vast timber resources; during the year ended June 30 1924 about 5,000,000 ft. of mahogany and cedar had been shipped from the lumber camps on the Rio Congo.

**Communications.**—There are three railways with a total mileage of 257. Of these the Panama Railroad Co. (U.S. Govt.) has a line between Colón and Panama, a distance of 48 miles. The Chiriqui Railway, owned by the Government, runs from Pedrigo to Boquete, a distance of 33 m., with two branches, one of 17 m. from David to La Concepción, the other from Dolega to Potrerillos, a distance of eight miles. The railway operated by the United Fruit Co. and constructed primarily for the banana trade has a mileage of 151, radiating from Almirante. Approval has been given for a contract for the construction of a railway along the Atlantic coast from the mouth of the Chagres river to Almirante. In 1923 a loan of \$4,500,000 was obtained by Panama in New York City to provide funds for highway construction. Before midsummer 1925, 125 km. had been constructed. The system connects Santiago, Las Tablas and Menabé with Panama City by way of Agua Dulce, Penonomé, Ancón, Chamé and Chorrera. Nearly 30 steel bridges have been built.

Goethals, *Government of the Canal Zone* (Oxford, 1915), also *The Panama Canal* (1916); W. H. Koebel, *Central America*, South American series (1917); H. G. James and P. A. Martin, *The Republics of Latin America* (1923). (H. I. P.)

**PANAMA CANAL** (see 20.666).—The construction period of the Panama Canal covered about 10 years, but the actual work of construction was accomplished in about seven years; the first three years were devoted to preliminary preparation, during which time the thorough sanitation of the Canal Zone was accomplished, yellow fever banished, an operating plant assembled, a working force gathered, living quarters erected and a food supply provided. Reservoirs were built which furnished an ample supply of pure water to the Canal force, and to the cities of Colón and Panama, in which water- and sewer-systems were built. An out-of-date railway system was converted into an adequate one with a thoroughly modern equipment of rails, locomotives and cars.

**Beginning of the Work.**—The first commission was in office only a year (1904-5) and accomplished little beyond formulating plans and ordering necessary supplies. The second, with John F. Stevens as chief engineer and afterwards as chairman also, reconstructed the railway system, assembled the operating plant, collected an efficient working force and provided for it quarters, food and all necessary supplies. It also constructed wharves and docks at both terminals, and machine shops in which the locomotives, cars, steam shovels, etc., shipped in parts from the United States were put together. President Roosevelt visited the Isthmus in Nov. 1906, the visit being notable as the first instance in which an American president had passed out of the U.S. territory while in office. Col. Goethals, of the Engineer Corps of the U.S. Army, was appointed chairman and chief engineer of the third commission, on the resignation of Mr. Stevens (April 1907).

This commission was composed of four army engineers, an army doctor, one navy engineer and one civilian. President Roosevelt, who was convinced that the best results could not be obtained through an executive body of seven members, issued an executive order placing supreme power in the hands of Col. Goethals, abolishing the commission as an executive body, and making its members, who were heads of departments, subordinate to him, giving Col. Goethals all civil, military and other powers in the Canal Zone, and this course was subsequently approved in the Act of 1912 for the government and operation of the Canal after its completion.

**Excavation and Slides.**—During the next five years 75% of the entire excavation of the Canal was accomplished. The original plans provided for a total excavation of 95,000,000 cu. yd. and a total cost of \$190,000,000 exclusive of \$40,000,000 paid to the French Canal Company, \$10,000,000 paid to the Panama Republic, and the cost of sanitation and civil administration. Changes made in the basal dimensions with the approval of President Roosevelt increased

the total excavations to 175,000,000 cu. yd. and the estimated cost to \$375,210,000, inclusive of payments to the French Canal Co. and the Republic of Panama. When the Canal was declared formally complete and opened by President Wilson July 12 1920, a total of about 240,000,000 cu. yd. had been excavated and the total cost, exclusive of expenditure for naval and military defence, was only \$366,650,000, of which \$10,000,000 was for "slides" or breaks in walls of the Cut of which there were about 30 at different times, affecting an area of 220 ac. and increasing the excavation by 30,000,000 cu. yards.

### I. ENGINEERING FEATURES

**Gatun Dam.**—The Panama Canal is a huge water bridge rather than a canal, for its surface for the greater part of its length is 85 ft. above sea level and is held in place by dams at either end. The largest and most important dam is at Gatun, on the Atlantic side. It spans the northern and lower end of a deep valley through which the Chagres river formerly flowed to the sea. It is  $1\frac{1}{2}$  m. long measured on its crest, half a mile wide at the base, 400 ft. wide at the water surface, 100 ft. wide at the top; and its crest is at an elevation of 105 ft. above sea-level. It is really two dams in one, for in its centre there is a natural hill or rock 110 ft. high. In this the spillway of the dam is constructed, and against its two sides rest the two sections of the great dam. The dam itself contains 23 million cu. yd. of material. Its outer portions are composed of rock and earth mainly from the Cut, and its centre or core of material drawn by hydraulic process from pits above and below the dam. This material is a natural mixture of sand and clay which in a watery condition flowed into the interstices of the rock and clay of the structure, making the whole at the centre a rubble-wall firmly cemented together and thoroughly impervious to water. Of the entire length of the dam only 500 ft. are exposed to the maximum waterhead of the lake, which is 85 to 87 feet. In 1919, after an exceptionally light rainfall, the maximum level of the lake was 87.16 ft. in Dec.; and in May 1920, 81.65 feet. The spillway is a concrete-lined channel, 1,200 ft. long and 285 ft. wide, the bottom being 10 ft. above sea-level, sloping to sea-level at the lower end.

Across the lake-opening of the channel is a concrete dam in the form of an arc of a circle, making its length 808 ft., although it closes a channel with a width of only 285 feet. The crest of this dam is 69 ft. above sea-level, or 16 ft. below the normal level of the lake. On the crest are 13 concrete piers with their tops 115.5 ft. above sea-level, and between these are 14 regulating gates of the Stoney type which move up and down on roller trains in niches in the piers. The gates permit a discharge of water greater than the maximum known discharge of the Chagres river during a flood. Near the north wall of the spillway is a hydroelectric station capable of generating, through turbines which are supplied with water from the lake through a forebay, sufficient electricity to meet all demands, including the lighting of the Canal and all Canal Zone towns and buildings; the machinery of the locks, the machine shops, dry-dock and coal-handling plant; and the telephone and telegraph systems. There is an emergency Diesel electric plant at Miraflores.

**Dams on the Pacific Side.**—At Pedro Miguel, at the south or Pacific end of the Cut, the water is held at summit level (level of Gatun Lake and the Cut, normally 85 ft. above the sea) by Pedro Miguel Lock and two flanking dams extending from the side walls of the lock to hills on either side. The distance between the hills at elevation 92 ft. is 2,000 feet. The situation of the lock at the base of Cerro Luisa made it practicable to connect with that hill by a short concrete wall, 260 ft. in length, subsequently covered with earth. On the west side a rock and earthen dam was built with a puddled and rolled impervious core, 1,400 ft. in length. The minimum width of base is 800 ft., the side slopes, 8 to 1, the top, 105 ft. above sea-level. The maximum head of water to which the dam is subjected is 40 ft., the average between 25 and 30 feet.

The Pedro Miguel Lock raises or lowers ships 31 ft.—the difference between the summit level of 85 ft. and the normal surface of Miraflores Lake—54 ft. above sea-level. The Miraflores Lake is a mile in length, and its waters are retained by the Miraflores Locks and flanking dams. The east dam at Miraflores is of concrete, and the greater part of it is the spillway of Miraflores Lake. This spillway is 432 ft. in length, with the crest of its dam 38.67 ft. above sea-level, and the supporting piers for the gates rising to 85.17 ft. above sea-level. Eight gates, similar to those in the Gatun Spillway, each 47 ft.

101 in. long by 19 ft. in height, and weighing 44 tons each are operated in the same way as the 14 gates at Gatun; but the dam at Miraflores is straight, instead of being in the form of an arc, as at Gatun. The west dam at Miraflores is of earth and rock and extends almost parallel with the axis of the locks to a hill to the south. Its length is 2,300 ft., top 70 ft. above sea-level, width of top 40 ft., and slope of sides approximately 12 to 1. It contains 661,000 cu. yd. of soft hydraulic material and 1,500,000 cu. yd. of rock and earth.

**The Locks.**—All locks are in duplicate, constructed in the same manner, and their chambers, with walls and floors of concrete, have the same usable dimensions—1,000 ft. long and 110 ft. wide. There are six pairs, making 12 in all. The side walls are from 45 to 50 ft. wide at the surface of the floor, are vertical on the chamber side, and narrowed on the outside from a point  $24\frac{1}{2}$  ft. from the floor, by means of a series of steps each 6 ft. long, to a width of 8 ft. at the top. A culvert 254 sq. ft. in cross-section, extends the entire length of each middle and side wall, and from each of these large culverts, smaller culverts, 33 to 44 sq. ft. extend to holes in the floors. Fifteen feet above the top of the culvert in the middle wall there is a U-shaped space 19 ft. wide at the bottom and 44 ft. at the top. This space is divided into three storeys; the lowest for drainage; the middle for wires that carry the electric current to operate the gates and valve machinery installed in the centre wall; and the upper a passage-way for the operators. All lock walls are 81 ft. high, except in the lower pair of locks at Miraflores, where they are 82 ft. because of the extreme tidal oscillations of about 21 ft. in the Bay of Panama. In the walls at Gatun there are 2,068,000 cu. yd. of concrete, and in those on the Pacific side 2,440,000 cu. yards. All lock walls rest on rock foundations. The approach wall at the north entrance at Gatun, 1,031 ft. long, rests upon piles driven from 35 to 70 ft. into the earth; that at the south or lake entrance 1,009 ft. long, rests on piles reaching to rock, in some places over 100 ft. below sea-level. Cellular form of reinforced concrete is used in all approach walls, except those of the lower locks at Gatun and Miraflores, where mass concrete is used because of the effect of salt water on steel reinforcement.

**Lock Gates.**—The lock gates, each composed of two leaves, are 65 ft. wide, from 47 ft. 4 in. to 82 ft. high, 7 ft. thick, and weigh from 390 to 730 tons. There are 92 leaves in all, and their combined weight is 60,000 tons. Each is a huge webbed steel box, the girders of which are covered with a steel sheathing. All portions of the interior are accessible, with watertight compartments providing for the adjustment of the buoyancy so as to control within limits the dead load on the bearings, making the leaf practically float in the water. This watertight compartment is subdivided vertically into three sections, each independently watertight, so that if the shell should be broken or leak, probably only one section would be affected. An air shaft, 26 in. in diameter, runs from the bottom compartment up to the top of the gate, and is also watertight where it passes through the upper half of the leaf.

The girders are made with manholes through the webs, providing communication from the top to the bottom of the leaf, and are connected by several sets of vertical transverse diaphragms of solid plates, running from top to bottom of the leaf, thus making a cellular construction, and dividing the spaces between the horizontal girders into small pockets, all of which are accessible through manholes. Each leaf rests at the bottom of its heel post upon a hemispherical pivot of forged nickel steel, and is hinged at the top to the masonry of the lock wall. It swings free on the pivot like a door, without wheels or other support beneath it. Intermediate gates are used in all except one pair of locks, and divide the space into two chambers, one 600 and the other 400 ft. in length. This makes possible a saving of water and time in locking small vessels through, for 95 % of the vessels navigating the high seas are less than 600 ft. in length. The highest gates and the highest lock walls on the Canal are those of the lower locks at Miraflores, and these locks are the only ones which have no intermediate gates. The total lift from mean sea-level to the level of Miraflores Lake, 54 ft., is divided equally between the upper and lower locks. The depth of water on the mitre sills is 40 feet.

The locks are filled and emptied through the large and smaller culverts. The large culverts are controlled at points near the gates by large valves, and each of the small culverts feeds in both directions through the laterals, thus permitting the passage of water from one twin lock to another, effecting a saving of water if desired. The average time required to fill or empty a lock chamber is 8 min. if both centre and side wall culverts are used, and 12 min. if only one culvert is used. The average time to pass a vessel through the three flights at Gatun Locks is an hour, from arrival to clearance; for the one lift at Pedro Miguel half an hour, and for the two flights at Miraflores three-quarters of an hour. The time of passage of a vessel from one terminal port of the Canal to the other is 7 hours. The transit is conducted under a time schedule in order to use to best advantage the lock operating forces, assure safety in passing and conserve water in times of need.

**Passage of Locks.**—With the exception of small craft no vessel can pass through the locks under its own power. On arrival at the locks it is taken in tow by towing locomotives or "electric mules." These locomotives operate on cog tracks on the lock walls at the rate of two m. an hour. The usual number required for a vessel is six: two ahead, one on each wall, two slightly forward of amidships, one on each

side, the four imparting forward motion to the vessel; and two astern, one on each side, to aid in keeping the vessel in a central position and in bringing it to rest within the chamber while the emptying or filling is carried on. Smaller vessels are handled with four locomotives, the two amidships being dispensed with; while very large craft may use eight. The movements of the locomotives are directed by the pilot from the bridge of the vessel. Each locomotive is equipped with a slip drum, towing windlass and hawser, which permit the towing line to be taken in or paid out without actual motion of the locomotive on the track. The locomotives run on a level, but in passing from one lock to another they climb heavy grades.

Before a lock can be entered, a fender chain, stretched across the walls of the approach, must be passed. If all is proceeding properly, this chain is dropped into its groove to the bottom of the channel. If by any chance the ship is moving too rapidly for safety, the chain remains stretched and the vessel runs against it. The chain, which is operated by hydraulic machinery in the walls, then pays out slowly by automatic release until the vessel is brought to a stop. The chain, which weighs 24,098 lb., and is stronger than any previously made, is capable of stopping a 10,000-ton ship running at 4 m. an hour within 73 ft. or less than the distance between the chain and the first gate. If the vessel should get away from the towing locomotive and, breaking through the chain, ram the first gate, there is a second gate 50 ft. away, protecting the lock, which arrests further advance. When the leaves of this gate swing open, the vessel is towed in, and the gate is closed behind it. Then, from 105 openings placed at regular intervals in the lock floor, water pours in, lifting the vessel to the level of the lock above. This inflow, coming equally from all points, does not move the ship from a stable position. The gates are never opened or closed with a head of water on either side of them. The process of lifting is repeated until the vessel reaches the lake level. At all times the vessel is in full view of the men who are controlling it and as safe as if tied to a wharf.

The gates are opened and closed by a powerful machine invented by Edward Schildhauer, an electrical engineer in the employ of the Isthmian Canal Commission. It consists of a crank gear or wheel moving through an arc of 197°, placed horizontally in the lock wall. To the outer rim of the wheel is attached a strut or connecting rod which is fastened to the top of a lock gate 17 ft. from the pintle or hinge. When the wheel turns in either direction the gate leaf is opened or shut, the operation taking two minutes. The crank gear, constructed of cast steel, is 19 ft. 2 in. in diameter and weighs approximately 35,000 pounds. It is connected with an electric motor, and a small electric switch sets it in motion. Every operation in the passage of a vessel through the lock, except the movements of the towing locomotives, is controlled by one man in a building at the top of the centre wall commanding an unobstructed view of every part of the locks. He has before him a control board table 64 ft. long and 5½ ft. wide, which is a complete model of the locks in duplicate, with switches and indicators in the same relative positions the machines they control occupy in the lock walls. Standing by this board the operator throws the electric switches, and in response to his action he sees in the model the fender chains rise and fall, the gates open and close, the water rise and fall in the locks, and knows the exact position of the vessel at every stage of its progress. Each gate, each valve for letting in the water to the culverts and each fender chain is operated by a separate motor mounted near the machinery in chambers in the lock wall. In each machinery chamber there is a starting panel containing contactors by which current is applied to the motor, and these panels in turn are controlled from a main unit in the central control house. Some of the machinery chambers at Gatun are 2,700 ft. distant from the point of control, 90 % of them are within 2,000 ft., and 50 % within 1,200 feet.

## II. COURSE AND ACCESSORIES

The length of the Canal from shore line to shore line is 42 m., and from deep water in the Atlantic to deep water in the Pacific 50 miles. The Canal does not, as is generally supposed, cross the Isthmus from east to west. It runs due south from its entrance in Limon Bay, through the Gatun Locks to a point in the widest portion of Gatun Lake, a distance of 11½ m.; it then turns sharply toward the east and follows a course generally south-eastern till it reaches the Bay of Panama. Its terminus near Panama is about 22½ m. east of its terminus near Colón. In passing from the Atlantic to the Pacific a vessel enters the approach channel in Limon Bay, which has a bottom width of 500' ft. and extends to Gatun a distance of seven miles. At Gatun it enters a series of three locks in flight which lift it 85 feet. It then enters upon Gatun Lake, which covers an area of 164 sq. m. with a depth varying from 45 to 87 ft. and contains 183,136,000 cu. ft. of water. The Canal has a channel varying from 500 to 1,000 ft. in width for a distance of 24 m. to Gamboa, where the Cut passage begins. Through the lake a vessel may steam at full speed, without any risk.

The channel through the Cut, a distance of about 8 m., has a bottom width of 300 ft. and a depth of 45 ft., and extends to the locks at Pedro Miguel, the Pacific end of the water bridge. At Pedro Miguel the vessel is lowered in the single lock 31 ft. to a small lake, at an elevation of 54 ft. above sea-level, through which the vessel passes 1 m. to the two locks at Miraflores. These drop it to sea-level, and through an approach passage 8 m. long, with a bottom width of 500 ft., it passes into the Pacific. The Cut has eight angles and at these the channel is widened sufficiently to allow a 1,000-ft. vessel to make the turn. The smallest angle is 7° 36' and the largest 29° 59'. In the whole Canal there are 22 angles, the total curvature being 600° 54'. The sharpest curve is 67° 11'. The Canal is lighted from end to end by electricity and gas. There are concrete lighthouses for range lights on the hillsides, and beacons in the Cut, in which electricity is used. The channel through Gatun Lake is marked with floating buoys lighted with compressed acetylene dissolved in acetone. The most powerful electric lights are those of the approach channels, which are visible for from 12 to 18 nautical miles. The beacons and gas-buoy lights are 850 candle-power. White and red lights are used, and in order to eliminate the possibility of confusing the lights with one another, and with the lights on shore, all range lights, beacons and buoys have individual characteristics, formed by flashes and combinations of flashes of light and dark intervals. The electric lights on the locks are suspended from brackets on concrete columns 34 ft. high, and clustered under concrete hoods in such a way as to light the lock chambers and not penetrate along the axis of the Canal.

*Breakwaters.*—Long breakwaters have been constructed near the approach channels in both oceans. One in Limon Bay, or Colón harbour, called the West Breakwater, extends from the bay from Toro Point at an angle of 42° 53' northward from a base line drawn from Toro Point to Colón Light, and is 11,526 ft. in length, 15 ft. wide at the top and 10 ft. above mean sea-level. A second, also in Limon Bay, known as the East Breakwater, is without land connection, one m. in length and runs in an easterly direction at nearly a right angle with the Canal channel. It has a lighthouse on the channel end. The West Breakwater protects the harbour against "northers," very severe gales which are likely to blow from Oct. to January. The East Breakwater prevents silting in the Canal channel. The breakwater at the Pacific entrance extends from Balboa to Naos I., a distance of 17,000 feet. It lies from 900 to 2,700 ft. east of, and for the greater part of the distance nearly parallel to, the axis of the Canal prism, varies from 20 to 40 ft. in height above mean sea-level and is from 50 to 3,000 ft. wide at the top. It was constructed for a twofold purpose; first, to divert cross-currents that would carry soft material from the shallow harbour of Panama into the Canal channel; second, to furnish rail connection between the islands and the mainland.

*Permanent Canal Buildings.*—Upon the completion of the Canal a number of villages along the line occupied during the construction days were abandoned, the sites of several being covered by the filling of Gatun Lake. The buildings in good condition were transferred to the permanent towns located at the ends of the canal and adjoining the locks. Culebra, the former headquarters of operations, situated on the west bank of the Cut near its deepest part, was turned into an army post. The permanent headquarters were located at Balboa Heights, and the offices of the departments centred in a large 3-storey concrete administration building situated on a hill 100 ft. above sea-level, and overlooking the Pacific entrance to the Canal. On the hill in the rear of this building are the residences of the governor and other officials. On the low land in front of the building, in a site which was formerly a tidal swamp and was raised to 20 ft. above sea-level by filling with material from the Cut and hydraulic fill from excavation in the harbour, is the town of Balboa. This is laid out on both sides of a central avenue called the Prado, and contains permanent buildings of concrete blocks roofed with red tile. In addition to the dwellings of employees there are a police station, post office, fire station, sanitary office, dispensary, clubhouse, a community house conducted by the Catholic Church, an army and navy Y.M.C.A., restaurant, churches, lodge hall, schoolhouse and playground. Effective municipal layout in a setting of great natural beauty

and an abundance of trees and shrubs make the villages very attractive places of residence. The streets are of concrete with asphalt surfacing, and the number of automobiles in use is noticeably large.

**Terminal Facilities.**—At the ports on both oceans have been constructed facilities ample for commercial shipping and the naval needs of the United States. Modern piers, 1,200 ft. in length by 240 ft. in width, with enclosed sheds, built of reinforced concrete and steel, are ample for the transshipping of cargo and the storage of goods consigned there for orders. At the Pacific end, at the foot of Sosa Hill, Balboa, are marine and railway repair shops, foundry, etc., covering 60 ac., thoroughly equipped and including a dry dock having a usable length of 1,000 ft. and entrance width of 110 ft., capable, like the locks and other parts of the Canal, of accommodating any vessel afloat. The depth over keel blocks is 43 ft. at mean tide. Smaller shops and a dry dock 300 ft. long and 48 ft. wide with depth of 13½ ft. are operated at the Atlantic end. Coaling plants capable of rapid bunkering are operated at both terminals, as well as oil-pumping plants connected with storage tanks for fuel oil, Diesel oil and gasoline. Storehouses supply all kinds of ship chandlery and repair material, as well as foodstuffs, beef and other fresh meats and cold storage supplies, ice, etc. Ships' every need of repair or supply can be met. Radio stations for communication with ships are operated by the U.S. Navy at Cristobal and Balboa, and also at Cape Mala, 90 m. south of the Pacific entrance, and a high-power station, primarily for government communication with the United States, is situated at Darien, midway of the Isthmus. Salvage tugs and other wrecking equipment are available for use of vessels within a radius of 1,000 m. or more of the Canal. Hotels and hospitals are situated at both terminals.

**Fortifications and Military Occupation.**—By executive order dated Dec. 5 1912, President Taft declared that "all land and land under water within the limits of the Canal Zone are necessary for the construction, maintenance, operation, protection, and sanitation of the Panama Canal," and title to all such land was acquired by the Govt. of the United States. The Canal Zone is thus a military reservation, and the only activities carried on by other than government forces are on land rented to steamship interests and to agriculturists under revocable licences. Heavy fortifications have been built at both entrances to the Canal and brigade posts established near the locks. Both the army and the navy have aerial forces at the Canal, and a base for submarines is maintained at the Atlantic end. The total military force is 10,000 men.

**Panama Railroad.**—The Panama Railroad extends between Colón and Panama on the eastern side of the Canal, and is 47.61 m. long. A branch line, extending from Pedro Miguel to Las Cascadas and crossing the Canal on a floating bridge at Paraiso, was discontinued Jan. 1 1921. The railroad as built in 1850-5 followed the course of the Chagres from Gatun to Gamboa, and was for the most part on the west side of the route of the Canal. With the building of the Canal it was necessary to relocate the railroad throughout practically its whole length. The construction of the original railroad was done by an American company in the years 1850-5 under great difficulties; its completion antedated by 14 years the completion of the first transcontinental railroad in the United States. At that time gauges had not been standardised, and a width of 5 ft. was adopted for the Panama Railroad which has been maintained since. The railroad was an essential factor in the construction of the Canal, and is an important adjunct to its operations. It is equipped with 90-lb. rails, rock-ballasted track, and automatic signals. It uses modern American rolling-stock, including oil-burning locomotives.

### III. ADMINISTRATION AND FINANCE

Under an Act of Congress, approved Aug. 24 1912, the Panama Canal is governed and operated, and the Canal Zone is governed through a governor of the Panama Canal, appointed by the President, with the approval of the Senate, for a term of four years, at a salary of \$10,000 a year. In addition to the operation of the Canal, the governor has official control and jurisdiction over the Canal Zone and performs all duties in connection with its civil government, it being held, treated, and governed as an adjunct to the Canal. There is one U.S. District Court in the Canal Zone, with the same jurisdiction and procedure as the same courts in the United States, the judge of which is appointed by the President. Appeals are made to the Circuit Court of Appeals of the Fifth Circuit of the United States. At Balboa

and Cristobal there is a magistrate's court for minor cases, the judges being appointed by the governor. Gen. Goethals was the first governor and served until Jan. 11 1917, when he resigned and was succeeded by Col. Chester Harding, U.S.A., who held the office until March 27 1921, when he was succeeded by Col. Jay J. Morrow, U.S.A. The latter resigned in Oct. 1924, and was succeeded by Col. Meriwether L. Walker, U.S.A.

The organisation on the Isthmus includes a number of departments and divisions in charge of the various activities, as follows: Dept. of Operation and Maintenance, including the Marine Div., Mechanical Div., Dredging Div., Section of Lock Operation, Electrical Div., Div. of Municipal Engineering, Fortifications Div.; and several sections; the Supply Dept., made up of the Quartermaster section, Subsistence section, Commissary Div., Cattle Industry and Plantations, and Hotel Washington; the Accounting Dept.; the Health Dept.; the Executive Dept. and the Panama Railroad. The Panama Canal has an office in Washington, D.C., and the Panama Railroad Co. has an office at 24 State street, New York.

**Canal Zone Population.**—A census of the Canal Zone taken in 1925 showed a total population of 37,011, of which 27,151 were civilians and the remainder military. The civilians included 2,301 adult male Americans; 2,413 American women; 2,399 American children, and people of other nationalities as follows: men, 6,928; women, 4,563; children, 8,547.

**Canal Force.**—The working force at the end of June 1925 numbered 12,270, of whom 2,885 were Americans, chiefly in official and clerical positions and skilled trades, and 9,385 were alien labourers, chiefly West Indian negroes. The apparent discrepancy between these figures and those of the Canal Zone census is due to the fact that many of the labourers live in the cities of Panama and Colón, which are not within the Canal Zone.

**Tolls.**—The Hay-Pauncefote Treaty between Great Britain and the United States, abrogating and succeeding the Clayton-Bulwer Treaty, was ratified on Dec. 16 1901. It contained this clause:

The Canal shall be free and open to the vessels of commerce and of war of all nations observing these rules, on terms of entire equality so that there shall be no discrimination against any such nation or its citizens or subjects in respect of the conditions or charges of traffic or otherwise. Such conditions and charges of traffic shall be just and equitable.

In 1912 Congress passed an Act for the operation and government of the Panama Canal, which was approved by President Taft on Aug. 24 of that year, and which contained the provision that "no tolls shall be levied upon vessels engaged in the coastwise trade of the United States." A formal protest against this exemption was made by Great Britain on the ground that it was a violation of the Hay-Pauncefote Treaty. In June 1914, under a special appeal from President Wilson, Congress passed a bill which repealed the Exemption Act of 1912. This was approved by President Wilson on June 15 1914. Under authority given to him by the Panama Canal Act of Aug. 24 1912, President Wilson issued a proclamation, on Nov. 21 1913, fixing the canal tolls at \$1.20 per net ton of net capacity as determined by the Panama Canal rules of measurement. On Feb. 15 1915 President Wilson issued supplementary instructions that where application of the \$1.20 per-net-ton rate produced a sum in excess of the sum produced by the application of the \$1.25 rate on net registered tonnage as determined by the U.S. rules of measurement, the excess amount should be uncollectable. The effect of this ruling was to reduce by approximately 14% the revenue from tolls paid by ships of all nationalities using the Canal.

During the first six years of operation there was a marked increase in traffic notwithstanding the fact that the World War everywhere prevented the normal development of ocean-going commerce. After the entry of the United States into the War there was a decrease in commercial traffic, due to the diversion of certain lines of ships to trans-Atlantic service, which was more than offset by the increase in traffic growing out of the War, chiefly on account of the development of the nitrate trade with the Pacific coast of South America. With the return of normal conditions after the War traffic rapidly increased.

**Canal Traffic.**—The number of commercial transits, the amount received from tolls and other collections, and the current expenses of

maintenance and operation for the fiscal years ending June 30 1915-25, are shown in the following table:—

| Fiscal year | Number of commercial transits | Tolls and other transit revenues | Current expenses of operation and maintenance |
|-------------|-------------------------------|----------------------------------|-----------------------------------------------|
| 1915        | 1,072                         | \$ 4,343,383.69                  | \$4,123,128.09                                |
| 1916        | 760                           | 2,558,542.38                     | 6,909,750.15                                  |
| 1917        | 1,806                         | 5,808,398.70                     | 6,788,047.60                                  |
| 1918        | 2,068                         | 6,411,843.28                     | 5,920,342.94                                  |
| 1919        | 2,028                         | 6,354,016.98                     | 6,112,194.77                                  |
| 1920        | 2,478                         | 8,935,871.57                     | 6,548,272.43                                  |
| 1921        | 2,892                         | 12,040,116.70                    | 9,328,300.14                                  |
| 1922        | 2,736                         | 11,385,592.32                    | 7,919,017.63                                  |
| 1923        | 3,967                         | 17,691,844.06                    | 7,690,777.56                                  |
| 1924        | 5,230                         | 24,681,853.89                    | 8,373,905.39                                  |
| 1925        | 4,673                         | 21,582,618.16                    | 8,116,693.44                                  |

Among nations the chief users of the Canal were the United States and Great Britain. The number of vessels passed each year for these nations and for all other nations was as follows:—

| Fiscal Year | United States | Great Britain | All other nations |
|-------------|---------------|---------------|-------------------|
| 1915        | 470           | 465           | 153               |
| 1916        | 238           | 358           | 191               |
| 1917        | 464           | 780           | 632               |
| 1918        | 628           | 699           | 803               |
| 1919        | 786           | 602           | 637               |
| 1920        | 1,129         | 753           | 596               |
| 1921        | 1,210         | 972           | 710               |
| 1922        | 1,095         | 935           | 706               |
| 1923        | 1,994         | 1,065         | 908               |
| 1924        | 2,947         | 1,265         | 1,018             |
| 1925        | 2,326         | 1,211         | 1,136             |

The following is the saving in nautical miles, effected by the Panama Canal from European ports to ports on the west coast of America, to Hawaii and to New Zealand:—

| To                   | From      |         |         |          |           |
|----------------------|-----------|---------|---------|----------|-----------|
|                      | Liverpool | Hamburg | Antwerp | Bordeaux | Gibraltar |

<sup>1</sup> Distance less via Suez.

The notable increase in business in 1924 was due mainly to the development of oil-fields in California, whence large quantities of crude oil were shipped in tank steamers to refineries on the Atlantic seaboard. These shipments declined in the following year, but the loss was partly offset by the normal growth of other trades.

Public vessels of the United States, Panama and Colombia and vessels which are sent through the Canal solely for repair at the Balboa shops are exempt from the payment of tolls, and such vessels are omitted from the statistics in the above table. From the opening of the Canal to June 30 1925, they numbered 2,613, the majority of them being American naval vessels or army transports.

**PAN-AMERICAN CONFERENCES** (see 20.671).—The fourth Pan-American Conference was held at Buenos Aires in 1910, and during the same year the Pan-American Union building, erected through a gift of \$750,000 from Andrew Carnegie and \$250,000 contributed by the various republics of the Union, was formally dedicated.

During the three weeks following Dec. 25 1915, the second Pan-American Scientific Congress met in Washington. Amongst the speakers was President Wilson, who urged friendly settlement of international disputes by arbitration. The Congress appointed an International High Commission, which sat at Buenos Aires in April 1916. Improvement and extension of cable, telegraph and railway services between the countries was urged. A permanent International High Commission was established to promote uniform commercial laws throughout the countries represented in the Union. In Feb. 1918 the governing board of the Pan-American Union approved a plan to establish a Section of Education to promote better knowledge of the languages and history of the American republics through educational institutions.

In Nov. 1918 a Pan-American Federation of Labour Conference met at Laredo, Texas. Delegates were present from the United States, Mexico and Central America. An influenza epidemic interfered with South American attendance, Colombia alone being represented. A permanent federation was organised. Pan-American Child Welfare Congresses met at Montevideo, Uruguay, in Dec. 1918 and in May 1919; at the second meeting provision was made for establishing at Montevideo an International Bureau of Child Welfare. In June 1919 the second Pan-American Commercial Congress was held in Washington, and in the same city, in Jan. 1920, a Pan-American Financial Congress. The sixth International Sanitary Conference was held in Montevideo Dec. 12-20 1920. It re-organised the International Sanitary Bureau, which has been active in disseminating valuable bulletins on sanitation and public health.

In Jan. 1921 a convention was held in Mexico City with the object of promoting good relations between the labouring classes of the United States, Central and South America. It was attended by Samuel Gompers and other United States Labour leaders. In June 1921 Panama proposed the formation of a Pan-American League of Nations which should function on the American continent in the same manner as the League of Nations established by the Treaty of Versailles. The suggestion, however, did not meet with the approval of President Harding and no further action was taken in this direction. In Sept. 1921 a Pan-American Postal Congress was held in Buenos Aires, at which the postal rates between the countries of the Union were discussed.

*The Fifth Conference.*—The fifth Pan-American Conference was held March 25-May 3 1923 at Santiago, Chile, Henry P. Fletcher, U.S. Ambassador to Belgium, being head of the U.S. delegation. Delegations from all the American republics, except Bolivia, Mexico and Peru, were present, and a large number of subjects were discussed. A proposal by Uruguay that the principle of the Monroe Doctrine be adopted by all American States was not supported by the United States delegates, and was recommended for report to the next Pan-American Conference.

Similarly, an attempt to arrive at an agreement for the limitation of naval armaments failed on account of disagreement between Brazil, Argentina and Chile. Costa Rica strongly urged the establishment of an American Permanent Court of Justice but failed to obtain the support of the Conference, because the plan submitted included arbitration of questions involving the vital interests of nations, and the matter was referred to the commission of jurists at Rio de Janeiro in 1925.

Four conventions were completed and signed, viz., an agreement under which international disputes might be investigated and settled by a commission empowered to ascertain facts; a trade-mark convention, protecting users of trade-marks in the countries where ownership of the mark is acquired through registration; a convention to secure uniformity of nomenclature in the classification of merchandise; and one providing for the publicity of customs documents. No fewer than 73 resolutions were passed, one of the most important of which created four permanent committees to assist the Union in the study of (1) the best means of developing the economic and commercial relations between the American States; (2) the international organisation of labour in America; (3) hygiene in the countries of the American continent; and (4) the best means of developing intellectual co-operation, with especial reference to co-operation between the universities and the exchange of professors and students.

It was decided to hold the sixth Pan-American Conference at Havana, Cuba, within the following five years. In Sept. 1924 the International Pan-American Committee, consisting of men interested in developing closer Pan-American relations, proposed that Columbus Day, Oct. 12, should be observed annually as Pan-American Day, and the suggestion met with the approval of President Coolidge. The seventh Pan-American Sanitary Conference was held at Havana, Cuba, Nov. 5-15 1924, and the third Pan-American Scientific Congress met at Lima, Peru, in Dec. 1924.

Inman, *Problems in Pan-Americanism* (1921), and *Pan-American Conferences and their results* (1924); Pan-American Union, *List of Publications published or distributed* (1923); for the text of the conferences see *United States Supt. of Documents*.

**PAN-AMERICAN UNION** (see 20.671).—At the second Pan-American Conference, held at Mexico City, Oct. 1901-Jan. 1902, the International Bureau of American Republics was organised under a governing board of the diplomatic representatives of the American republics at Washington with the Secretary of State of the United States as chairman. At the fourth Pan-American Conference, held at Buenos Aires, July 12-Aug. 30 1910, it was decided that this International Bureau should be henceforth called the Pan-American Union. The same year the Pan-American Union building in Washington, D.C., erected through a gift of \$750,000 from Andrew Carnegie and other funds provided by the various republics, was dedicated and has since been maintained as the headquarters of the Union. At the fifth Pan-American Conference, held at Santiago, March 26-May 13 1923, the membership of the governing board of the Union was enlarged; and it was agreed that in future any American republic not having an accredited representative at Washington may nominate a special representative on the board.

The board is constituted of representatives of all the countries of America, except Canada and Guiana. Its purpose is to develop commerce, friendly intercourse, good understanding and the preservation of peace among the countries of America, and it is supported financially by quotas contributed by each country based upon their respective populations. It publishes a monthly bulletin embodying a record of Pan-American progress, and also special reports and pamphlets containing practical information on

Pan-American subjects. Its library, the Columbus Memorial Library, contains 55,000 volumes and a large collection of maps, photographs, lantern slides and negatives. In addition to its other activities, the governing board acts as an *ad interim* executive committee in the intervals between the Pan-American Conferences (q.v.).

**PANGALOS, THEODORE** (1878—), Greek soldier and politician, was born in Salamis of Albanian origin, and in 1895 entered the Athenian Military Academy, whence he proceeded to complete his studies in Paris. During the World War he commanded a regiment in Macedonia, in 1917 he held a post in the Ministry of War, in 1918 commanded the first infantry division and in 1919 was chief of the General Staff during the campaign in Asia Minor. When the revolution of 1922 dethroned King Constantine for the second time, he was chairman of the commission of enquiry into the responsibilities for the Asiatic disaster, and was consequently concerned in the execution of the six Royalist Ministers. He subsequently became Minister of War in the revolutionary Govt., and commander-in-chief of the Army of the Hebrons. At the elections of 1923 he entered the National Assembly as delegate from Salonika and chief of the Republican group. In the first Republican Cabinet of M. Papanastasiou in 1924 he was successively Minister of Law and Order (for the repression of brigandage) and War. On June 25 1925, by a bloodless *coup d'état*, he made himself Premier, then forced the Chamber to accept him, prorogued and subsequently dissolved it, took two Royalists into his Cabinet as a sign of "reconciliation," and on Jan. 3 1926 publicly proclaimed himself dictator; he had already been so in fact ever since he had thrown away the "parliamentary mantle" with which M. Papanastasiou had tried to cover the uniform of his former colleague. In April 1926 Gen. Pangalos was elected President of the Hellenic Republic in succession to Admiral Condouriotis.

**PAN-GERMANISM.**—Pan-Germanism is the name given to an imperialistic movement which, though it had long been gaining strength, received but little serious notice in Anglo-Saxon countries until the years immediately preceding the World War. Its importance may then have been exaggerated, yet there can be little doubt that it helped largely to popularise the belief that there had been at work in Germany forces bent upon ambitious schemes of territorial aggrandisement and political dominion.

*Its Two Aspects.*—There are, indeed, two aspects of Pan-Germanism—the purely national and defensive, and the outspokenly Chauvinistic and aggressive. The Pan-German is accustomed to describe his endeavours as merely designed to realise, under modern conditions, the ideas of men like Fichte, Arndt and other patriots who over a century ago looked to the time when the sundered German tribes would be gathered into one political fold. In the middle of the century the political economists Friedrich List and Wilhelm Roscher, both forward-looking in many ways, gave more purposive form to this vague notion of an all-embracing Germanic commonwealth. List dreamed of a German Empire extending from the Adriatic to the Black Sea, offering scope for German colonisation for centuries to come. He also predicted the eventual inclusion in that empire of Holland, holding that without control of the mouth of the Rhine Germany was "like a house whose front door is owned by a neighbour."

List's speculations would appear to have given encouragement and direction to the later more definite activities of the Pan-Germanist movement; for many of the imperialistic schemes which have been advanced by contemporary writers are only variations or augmentations—mostly the latter—of his ideas. List's influence can first be traced in the works of men like Paul A. de Lagarde, Gustav A. C. Frantz and Paul Dehn, who all wrote on the subject in the 'seventies or 'eighties of last century. Thus, in his *Deutsche Schriften*, Lagarde wrote:—

We must create a Central Europe which will guarantee the peace of the entire continent from the moment when it shall have driven the Russians from the Black Sea and the Slavs from the South and shall have conquered large tracts to the east of our frontiers for

German colonisation. We cannot let loose *ex abrupto* the war which will create this Central Europe. All we can do is to accustom our people to the thought that this war must come.

Frantz, too, in his book *Die Weltpolitik*, advocated the formation under German direction of a powerful confederation of States comprising, besides Germany, Austria, Holland, Belgium, Flanders, Lorraine, Switzerland, Franche-Comté, Savoy, and, in the East, the Balkan principalities and Russian Poland.

#### THE WAR PERIOD

During the years preceding the World War these ideas affected Germany and were reinforced by influential political names. They had been kept alive by a host of writers of unequal merit, among the most influential being Ernst von Halle, Friedrich Lange and Ernst Hasse. The special aspect of the Pan-German question to which Hasse devoted his pen was "frontier policy," the title of his best-known book. One of his favourite schemes was the hedging of the empire on its landward frontiers by a military *glacis*, a day's march wide, to be settled by the families of ex-non-commissioned officers and other picked men who had had a military training. This real *Landwehr* was to be the *rocher de bronze* of which Frederick the Great spoke, a bulwark against which the attacks of Germany's enemies would hurl themselves in vain. He also advocated the incorporation in the German Confederation of Belgium, Luxemburg, Holland and certain French frontier districts, as well as of Bohemia and Moravia (to be taken from Austria) and parts of Western Russia. For, he wrote, "We want territory even if it be inhabited by foreign peoples, so that we may shape their future in accordance with our needs."

It was only in 1891 that the Pan-Germans resorted to systematic organisation and propaganda. The colonial movement was then in full flood, and the idea of imperial expansion had captured the national imagination in a high degree. Five years before a congress of patriotic organisations had been called for conference in Berlin by Dr. Karl Peters, who later acquired a sinister notoriety. A loose federation of these bodies was formed for the more successful advancement of national interests, particularly territorial expansion, and Peters was for a time accepted as its head.

*A New League.*—In 1891 this federation was reconstituted as the General German League (*Allgemeiner Deutscher Verband*) under pressure of the strong public feeling evoked by the conclusion of the Zanzibar Convention of the previous year, by which Germany ceded to Great Britain a large part of her East African empire in exchange for the island of Heligoland. A membership of 20,000 appears to have been obtained, but this number gradually fell off to 5,000, until in 1894 the movement was taken in hand by Prof. Ernst Hasse of Leipzig, the municipal statistician and a member of the Imperial Diet. Simultaneously the name Pan-German League (*Alldeutscher Verband*) was taken; the machinery of organisation was improved and expanded; an energetic agitation by means of meetings, leaflets and a weekly news sheet *Pan-German Leaves* (*Alldeutsche Blätter*) was begun; and both members and money again came in freely.

The new League sought to create a world-wide national union of all the Germans, adopting as its motto the saying of the Great Elector of Brandenburg, Frederick William, the founder of the German colonial movement and the creator of the German navy, "Remember that you are Germans." The propagandist manifesto in circulation before the War set forth: "We must strengthen our national sentiment and bring home to the mass of our people, the fact that Germany's development did not end in 1871." The programme of action comprised the following measures:—

The quickening of the patriotic consciousness of Germans at home and the combating of all tendencies antagonistic to national development.

The solution of questions relating to the education and training of the young and the schools in the sense of Germanism.

The fostering and support of German national movements in all countries where our kinsmen have to struggle for the maintenance of Germanism; with the union of all Germans throughout the world.

(At the same time Germans living abroad were warned against direct interference in the internal affairs of the countries of their adoption.)

The promotion of an energetic German "policy of interests" in Europe and across the seas, and especially the carrying forward of the colonial movement to practical objectives.

Had the Pan-Germans kept their endeavours within the limits of the party's programme much later reproach might have been saved them. Individual members of the League, however, were not slow to supplement its avowed aims by all sorts of immoderate schemes of aggression in Europe, Asia Minor and Africa. As time passed and the relations of the Great Powers became increasingly strained, the League itself developed into a powerful piece of political machinery. Berlin was the administrative seat, but the organisation covered the whole country, which for purposes of agitation was divided into *Gauen* or regions, while the formation of branches in foreign countries was studiously furthered. There was an executive committee of 300 members, drawn from all parts of the Empire; there were special committees for various territorial and other questions; and national congresses were held at intervals. The fact that a large number of its members sat in the Imperial Diet gave to the League an excellent forum for the propagation of its ideas, and in all the more critical episodes and controversies in foreign politics during two decades prior to the War it proved an unwearied exponent of a spirited imperialistic policy.

Yet influential though the Pan-Germanist movement was before the War, and inflammatory as was much of its influence on public opinion, injustice would be done by identifying the German nation as a whole with its more aggressive propaganda. In the main the movement appealed to and was embraced by the powerful nationalist and Chauvinist parties—in other words, by the military men and the political reactionaries—for though many intellectuals supported the League the soberer heads among them kept aloof, and the historian Mommsen even called the Pan-Germans "patriotic idiots."

*Some Reflections.*—It would be equally unfair to draw general conclusions from the many extravagances which were uttered and written in Germany during the years of war. The real significance of the Pan-German propaganda at that time lay in the new importance attached to the idea of a Central European Confederation under German influence, now revived by Dr. F. Naumann in his book *Mittel-Europa*, perhaps the ablest contribution from the German side to the literature of a "New Europe," the expansion of the old Berlin-to-Bagdad programme into a grandiose scheme of empire extending from Antwerp and the North Sea to Basra and the Persian Gulf, and the claim to a vast consolidated colonial empire stretching across tropical Africa, to be acquired at the expense of France, Belgium and particularly of Great Britain. These ambitious projects are not recalled in order to prove that the war aims of Germany were more immodest than those of some of her enemies, still less for the purpose of pointing the contrast between aspiration and achievement, but rather as showing how many years of intensive Pan-Germanic agitation had clearly familiarised the national mind with the idea of imperial expansion as one which might be better realised by force of arms than by the slow methods of peaceful penetration.

When criticised, the Pan-Germanist is ready with his answer. "Put yourself in our position," he says; and the challenge is one to be met. Viewing the question from the German standpoint it is not difficult to discover facts and tendencies in national and international politics that explain, and within limits may be said to have condoned, the anxiety and spirit of unrest which settled upon Germans when, in 1885 or thereabouts, they began to feel the pressure of the population question, the growing need for new markets and the stirring of ambitions which pointed outwards. It is significant that the movement made its greatest advance when Mr. Chamberlain, Colonial Secretary from 1895 to 1902, was uttering his clear and resounding call to the Commonwealths of the British Empire to coalesce and to raise their frontier barriers, commercially, to the outer world. In the past the British Empire had opened its door freely to Germans as immigrants and traders, but they might be perhaps,

less welcome than before. Even had it been otherwise, the Germans chafed against the inequality in the partition of the undeveloped territories of the earth which compelled their emigrants to seek homes under alien flags and thus to be eventually lost to the fatherland. Further, while many German politicians feared a future agglomeration of the Anglo-Saxon races, the whole nation was haunted by the two-fold menace of a restless Russia in the east and of a France in the west unreconciled to the loss of territory in 1871.

These and other facts, weighing on an emotional and politically immature people, probably gained for Pan-Germanist ideas a hearing and a sympathy which in different circumstances might have been refused to them. When all due allowances have been made, however, it is but the more justifiable to say that Pan-Germanism stands condemned by its excesses. The great mistake of the Pan-Germans in the past has been that they allowed a justifiable national pride and an eager and natural hankering for more elbow-room to degenerate into hostile designs against other nations which, owing to historical reasons, had preceded Germany in the colonisation of the empty spaces of the earth, and that they so often avowed these designs with astounding candour. Since the War the Pan-German League, refraining from aggressive agitation, has concentrated its attention upon the task of strengthening the national sentiment and spirit, hardly tried by adversity. The latest revision of its statutes (March 1925) is substantially directed towards the political rehabilitation of Germany as a Great Power and the removal of the territorial and economic penalties imposed by the Treaty of Versailles. Stress is laid upon the maintenance and strengthening of the national spirit, the cultivation of the German individuality, the need for a powerful defence force, the recovery of the lands of which Germany has been deprived and the union of German-Austria with the Reich.

**Statistics.**—On the eve of the War the number of regional groups of the League was about 200, and the aggregate membership was 17,000, a number considerably below the maximum attained in 1902. In 1917 the groups numbered 250, with little change in the total membership. No official figures have been published since the War, but both the number of groups and the membership are believed to have greatly decreased. The representation enjoyed by the League in the Diet has likewise declined, for while as many as 38 members were identified with it in 1902 the number of such members had fallen to 17 in 1917 and since the War it has been quite insignificant.

**The Movement in Austria.**—The most important development of the Pan-German movement since the War is the great stimulus which it has received in Austria. There an autonomous League was formed in 1919 with an independent organisation; and working from Graz it has carried on a vigorous agitation in all parts of the country, and has even succeeded in making its influence felt in the German districts which have passed from Austrian rule under the Treaty of St. Germain. While its programme has much in common with that of the parent League, it specially emphasises union with Germany as the hope of the future.

That great enthusiasm is being thrown into the agitation is shown by the fact that up to 1925 200 district branches of the League had been organised, representing an enrolled membership of some 14,000. These Austrian reunion endeavours practically revive the Great Germany movement of the middle of last century. It is not the least strange of the ironies of history that an idea which at that time reft in twain the old German Bund should serve to-day as a symbol of national unity.

**BIBLIOGRAPHY.**—The German literature of the Pan-German movement is very large and inevitably of very unequal value. Better known writers include, besides those already named, Alexander von Peez, Albert Ritter, General Friedrich von Bernhardi, the Anglo-German Houston S. Chamberlain, Baron L. von Vietinghoff, Count von Reventlow, Albrecht Wirth, H. Frobenius and Friedrich Lange. Noteworthy German works on the League itself are an official survey of Pan-Germanic endeavours entitled *Zwanzig Jahre alldeutscher Arbeit und Kämpfe* (1910); Martin Wenck's *Alldeutsche Taktik (Pan-German Tactics)* (1917); and Burchard's *Geschichte des Alldeutschen Verbands* (1920). Of a number of works in English there

may be named Rowland G. Usher's *Pan-Germanism* (1913), and a translation of Charles Audler's *Pan-Germanism*, published in 1915. (W. H. D.)

**PAN-ISLAMISM.**—This word was first employed in journalistic literature in the early 'eighties of the 19th century to describe the efforts made in the Moslem world to bring about some unity of action in opposition to the Christian powers of Europe. Invented to express what was believed to be a new order of circumstances, the word has led to much misunderstanding, since it has obscured the facts that Mahommedan political theory has always embodied a hostile attitude towards unbelievers unless they submitted to Mahommedan rule, and that the ideal of the unity of all believers has formed an integral part of the religious outlook of Islam since its very inception. The only new circumstance in the relations between the Christian Powers and the various Moslem populations was that the expansion of the Press in the East and improved methods of communication have in modern times enormously facilitated the rapid circulation of ideas.

**The Unity of Islam.**—Since the Armistice in 1918 it has been as difficult for the present generation of Moslems to effect any realisation of the ideal unity of Islam as for the Mahommedan world during the last thousand years. The Moslem empire held together under the rule of the early Caliphs for little more than one century only. Personal ambition, racial distinctions, sectarian divisions and geographical conditions broke it up into fragments, and although the ideal of the unity of all believers was never abandoned and indeed formed the theoretical basis of the political theory and of both the religious and the judicial organisation of the greater part of the Mahommedan world, it has generally been left to theologians and journalists to bring forward schemes for its realisation, while *de facto* rulers and practical statesmen have ignored all such visionary attempts to re-arrange the political conditions of contemporary society. Indeed, throughout the whole history of Islam, the infrequency of any serious attempts to realise political unity and the lack of response when any such attempts have been made are more noteworthy facts than any so-called pan-Islamic movements. The Sanusis, who excited so much anxiety among the French in the latter part of the 19th century, succeeded in arousing little more than local interest instead of starting the conflagration which was expected to be about to put the whole of North Africa in a blaze. Similarly, the struggles for independence on the part of the Berbers in the Rif have attracted to their assistance no volunteers from other parts of the Mahommedan world, and the Turkish republic (one of the few independent Mahommedan states now surviving) has on more than one occasion made it clear that it does not concern itself with the fate of Mahommedan populations in other countries, even as it does not welcome interference in its own internal affairs on the part of non-Turkish Mahommedans.

**Attitude of Turkey.**—This attitude of aloofness on the part of the Turkish Govt. has dealt a severe blow at pan-Islamism, for those who worked for the unity of Islam during the 19th century had looked on Turkey as the rallying point of their efforts, and since the Armistice, pan-Islamic feeling has taken the form chiefly of anxiety for the fate of Turkey. While the settlement of the terms of the treaty was so long delayed, there was ample time for an organised excitation of feeling on the matter. As the Caliph was Sultan of Turkey and the Caliphate (*q.v.*) was the visible symbol of Islamic unity and served as the easiest basis for a popular appeal, the defence of this institution and the advocacy of its claims were placed in the forefront.

**India.**—The Khilafat movement was started in India in Oct. 1919, and in the following Nov. a Khilafat conference was held in Delhi. Shaikat Ali became secretary of it in the following year, and he and his brother, Muhammad Ali, were henceforward prominently connected with the movement. The latter headed a deputation to the Prime Minister in London in March 1920 and maintained that Islam required temporal power for the defence of the faith, that for this purpose the Caliph must retain adequate territories, including the whole peninsula of

Arabia, which was defined to include Syria, Palestine and Mesopotamia, and that the guardianship of the Holy Places must remain in his hands. The deputation returned disappointed, and in July 1921, in the Khilafat conference at Karachi, Muhammad Ali declared that military service under the present British Govt. was religiously unlawful for all Moslems, and he was consequently condemned to two years' imprisonment for making a statement likely to cause soldiers to fail in their duty. One result of the excitement stirred up in India was that in Aug. 1921 rebellion broke out among the Moplahs, a section of Mahomedans in Malabar, who declared their intention of establishing a Khilafat Govt., and murdered or forcibly circumcised a large number of Hindus.

The declaration of a Republic in Turkey in Oct. 1923 and the consequent abolition of the Sultanate, hitherto a concomitant of the Caliphate, contravened one of the main contentions of the Indian Khilafat party, namely that the dignity of the Caliphate demanded that the holder of this office should possess adequate power for fulfilling all his functions. Indian opinion found expression in a letter sent by H.H. the Aga Khan and the Rt. Hon. Ameer Ali in Nov. 1923 to Ghazi Ismet Pasha, in which they urged that "any diminution in the prestige of the Caliph or the elimination of the Caliphate as a religious factor from the Turkish body politic would mean the disintegration of Islam and its practical disappearance as a moral force in the world." The relation of the Caliphate to pan-Islamic aspirations was emphasised by representing this institution as "the link which binds the followers of Islam as a vast congregation." When the Caliphate was in peril from outside attacks, Mussulman feeling all over the world was violently agitated, and the Moslems of India gave their sympathy and support to the Turkish nation in the belief that "in fighting for their independence they were also fighting for the preservation intact of the institution which symbolised Moslem solidarity." The publication of this letter gave much offence to the Turkish Govt., which was little inclined to pay consideration to Indian opinion, since the Turks regarded the Indians as impracticable idealists and resented their failure to render assistance during the World War.

The abolition of the Caliphate by the Turkish national assembly in March 1924 excited still greater indignation in India, but in answer to numerous protests Mustafa Kemal Pasha (*q.v.*) defended the action of the national assembly, maintaining that the Caliphate had been a source of internal dissension in Turkey, that the ideal of a united Moslem State under the Caliph had never been realised but, on the contrary, had been a constant source of strife and duplicity among Moslems, and that the interests of the various Mahomedan peoples demanded that they should now organise themselves into separate governments. In view of these altered circumstances the Indian Mahomedans, who had hitherto been urging the claims of the Sultan of Turkey, had to adopt a new programme, and accordingly the Central Khilafat committee, at its meeting in Bombay in May 1924, resolved to endeavour to promote friendly relations and to strengthen the bond of brotherhood between the different Moslem countries and exchange communications regarding a settlement of the Caliphate question in accordance with the Sacred Law of Islam; at the same time, efforts were to be made to free the Peninsula of Arabia (as defined above) from the control of European Powers.

*Egypt.*—Less excitement was felt in Egypt, but the action of the Turkish national assembly was condemned by the whole body of the 'ulama, and various proposals were discussed for the revival of the office of the Caliph. Finally it was resolved to invite representatives of all the Moslem communities in the world to meet in Cairo to elect a new Caliph; such a congress, first proposed for March 1925, was postponed until May 1926.

*Java.*—In Java the first pan-Islamic congress was organised in Nov. 1922, when a telegram was sent to Mustafa Kemal Pasha, and the Javanese attitude towards the Caliphate question was discussed. At a later meeting in Dec. 1924 it was resolved to send delegates to attend the proposed Caliphate congress in Cairo, and this resolution was reaffirmed in Aug. 1925.

*Separatist Movements.*—Such efforts for united action in the Mahomedan world are less significant than the separatist and national movements, which have filled a larger place and have been of more permanent influence in the political life of Mahomedan countries. The basis of such nationalist feeling in the case of the Turks was racial, as also in the Soviet Mahomedan republics, which were organised as Kirghiz, Tajik or Turkoman; similarly in Arabia, where hostility to Turkish domination was exacerbated by the primitive pride of race and love of independence. Internal dissensions in Arabia even implicated the Indian supporters of the Khilafat movement, though by theory they were working for the unity of all believers; they regarded the action of King Husain in throwing off his allegiance to the Sultan of Turkey as an act of treachery towards Islam, and the Khilafat committee, in Aug. 1924, expressed their sympathy with Ibn Sa'ud, the Wahhabi Sultan of Nejd, when he invaded the territories of the King of the Hejazs, and in 1925-6 sent more than one deputation to him with proposals for the future government of the Hejaz. In Egypt the nationalist movement was territorial, and Moslems and Copts combined to assert the independence of their country; also in India, where the Swarajist and non-co-operation movements united Hindus and Mussulmans. In Java, Bolshevik influence in 1923 converted the Sarekat Islam (founded in 1910) into the Sarekat Ra'yat (Union of the People), which, unlike the movement out of which it sprang, takes no account of religion.

*Control of the Seas and of National Resources.*—The earlier writers on pan-Islamism view this movement as a possible menace to Christian Europe. The obstacles in the way of any such united activity on the part of the Mahomedan peoples have recently been discussed from a novel point of view in the *American Geographical Review* (vol. 14, New York, 1924); it is there pointed out that European control of the seas makes it impossible for any powerful combination of Moslem peoples to be effective, and that in the parts of the world inhabited by a predominating Mahomedan population there is a lack of those mineral resources which are necessary for the conduct of modern warfare, *e.g.*, phosphates are only found in those parts of North Africa that are under French control, manganese only in Georgia, tin only in Malacca, and petrol only in Baku.

**PANKHURST, EMMELINE** (1858- ), British suffragist, was born July 14 1858, the daughter of Robert Goulden of Manchester. In 1879 she married Richard Marsden Pankhurst (d. 1898), a barrister who drafted the Women's Property Act (1882) and an advocate of Women's Suffrage. Early interested in politics, she, during a short residence in London, took part in the strike of the match girls at Bryant and May's factory in 1886 and helped to found the Women's Freedom League three years later. Returning to Manchester in 1893 she acted for four years as a poor law guardian, and was afterwards a registrar of births and deaths and a member of the school board and education committee. After having been successively a member of the Liberal and Independent Labour parties, she decided to abandon everything for the cause of Women's Suffrage, and in Oct. 1903 was chiefly instrumental in the foundations of the Women's Social and Political Union on a non-party basis. Having failed to induce the Liberal party to make votes for women a part of their programme she utilised her organisation to oppose their candidates, took headquarters in London, held public meetings and organised processions and deputations to the House of Commons. On May 16 1906 she spoke for her society at a joint deputation of suffrage societies which met Sir H. Campbell-Bannerman at the Foreign Office. But the Liberal party being divided on the question, their leaders refused facilities for the discussion of private bills, and the methods of the W.S.P.U. increased in violence.

In 1908 Mrs. Pankhurst was arrested and imprisoned in Holloway for inciting to a breach of the peace by the issue of a handbill urging her followers to rush the House of Commons, and sentenced to three months' imprisonment. Claiming to be treated as a political prisoner, she defied prison rules and suffered solitary confinement, but was released before the expiration of her sentence on grounds of health. Next year she was again arrested for a technical assault and was again imprisoned, and at the end of the year paid a first visit to the United States. In 1910 there was a short lull in the movement pending the consideration of a moderate measure framed by a non-party committee of the House, but as the Government refused assistance the agitation was again resumed. The census was boycotted in 1911, and on her return from a second American visit at the end of the year Mrs. Pankhurst and her daughter directed a window-breaking campaign. Mrs. Pankhurst was sentenced to 9 months' imprisonment for inciting to violence in March 1912, but was temporarily released in June after refusing to take food and resisting forcible feeding, under the so-called "Cat and Mouse" Act. On her return from another visit to America she was re-arrested at Plymouth but soon again released, when she went abroad to her daughter, Christabel, who, having evaded the police, was at Paris.

In 1913-4 arson and the destruction of property were added to the methods of the W.S.P.U., and after the burning of Mr. Lloyd George's house at Walton, Mrs. Pankhurst was sentenced at the Old Bailey for inciting to commit felony, to three years' penal servitude, despite the jury's recommendation to mercy. But she served but a small part of this sentence as she refused both food and drink and even medical attention. Meanwhile, although steps were taken to crush the organisation, it continued to flourish, and funds came both from England and America, whilst public opinion began to assert itself against forcible feeding. The outbreak of war brought militancy to an end, and both Mrs. Pankhurst and her elder daughter lent their organisation to the cause of recruiting and the increase of munitions. At the first election (1918), after the concession of the vote, the latter contested Smethwick as an independent candidate. Christabel Pankhurst (b. 1880) had been the director of the skilful strategy of the militant movement which she had induced her mother to adopt. Several other members of the family also took part in it. One of them, Sylvia (b. 1882), opposed the War, became a Communist, and was imprisoned in 1920 under the defence of the Realm Act.

See E. Pankhurst's, *My Own Story* (1914); S. Pankhurst, *The Suffragette* (1911); A. Kenney, *Memoirs of a Militant* (1924).

**PANTALEONI, MAFFEO** (1857-1924), Italian economist and politician, was born at Frascati in 1857. After studying in Germany, he returned to Rome and attended the law faculty of the university where he took his degree. He specialised in the study of economics, and after teaching at Venice, Bari and Geneva was, in 1902, appointed professor of political economy in the University of Rome, a post which he held until his death. In economics he was the founder of the new scientific tendency, but he always managed to weld theoretical principles with the elaboration of concrete facts. Pantaleoni was deputy for Macerata in the XI. Legislature, and at first showed some sympathy for Radicalism and even Socialism; but when the latter abandoned its struggles for the elevation of the working classes and evolved into a system of proletarian organisations for exploiting its political influence he became an uncompromising opponent of the movement. On the outbreak of the World War he was an ardent pro-Entente interventionist. After the Armistice he opposed Bolshevism, and was a warm supporter of the Fascist movement, being one of the first senators created by the Fascist Government. In 1923 Pantaleoni was appointed Italian delegate on the League of Nations committee for the restoration of Austria's finances, of which he was president. He died in Milan Oct. 29 1924.

Pantaleoni's works include: *Teoria della traslazione dei tributi; Dell'ammontare probabile della ricchezza in Italia; Manuale di economia pura; Scritti vari di economia; Tra le incognite; Note in margine alla guerra, and Bolscevismo italiano.*

**PAN-TURANIANISM.**—The word *Turan*, from which the name of the Pan-Turanian movement is derived, is Persian. In the Persian epic it means the steppes and deserts of Central Asia, in contrast to the cultivated country of Iran or Persia. The people of Turan were the nomads who had constantly overrun Persia from the northeast. Since the beginning of the Christian era, these nomadic invaders from Turan have belonged linguistically to the peoples speaking the so-called agglutinative languages, in contrast to the languages of the Indo-European family. When modern European philologists wanted a common term to cover this agglutinative group they coined the word "Turanian" for the purpose.

Turanian researches were first taken up seriously by the Magyars of Hungary, and this for two reasons. The first reason was that the Magyar language belongs to the Ugro-Finnic branch of the agglutinative group, in contrast to most modern European languages, which are Indo-European. The second motive which influenced the Hungarians was not philological, but political. During the half-century before the World War, the Hungarian statesmen who largely controlled the foreign policy of the Austro-Hungarian monarchy were on the look-out for allies against the Pan-Slav movement which was being promoted by Russia, and seized on the fact that Turkish also was a Turanian language (though of a different branch from Hungarian), in order to commend to the Turks the idea of a Magyar-Turkish entente against the Slavs, a supposed linguistic kinship being assumed to imply a common racial origin. Thus the idea of Pan-Turanianism had an academic origin before it was exploited for political purposes, and it was first introduced to the Turks by a European nation, the Hungarians, who put it forward not in the Turks' interest, but primarily in their own.

Although the Magyar-Turkish entente eventually ripened into the military alliance between Turkey and the Central Powers during the World War, the Turks were never captivated by the concept of Pan-Turanian unity in the wider sense of a brotherhood between peoples speaking all branches of the Turanian family of languages. The Turks of the Ottoman Empire translated Pan-Turanianism into Pan-Turkism, that is, into the narrower idea of a brotherhood between all peoples speaking Turkish dialects, with an insistence upon the aboriginal Turkish element in their own Osmanli language and culture. These two sides of the Pan-Turanian movement as developed by the Ottoman Turks were equally important, and indeed were complementary to one another. The ancestors of the Ottoman Turks had travelled right across the Islamic world in order to reach their final home in Asia Minor and the Balkan Peninsula from their starting-point in Central Asia, and on their journey they had adopted the culture and religion of the Islamic world. The Ottoman Turkish dialect was enriched and overlaid with borrowings from Arabic and Persian, and the Ottoman Turks felt vividly their solidarity with all other Moslems, of whatever race or language, while retaining little or no sense of kinship with other Turks as such, especially if those other Turks belonged to different sects of Islam, or to non-Islamic religious communities.

A specifically Turkish national movement among the Ottoman Turks only began after the revolution of 1908, in which the Committee of Union and Progress overthrew the Sultan 'Abdül-Hamid, and the leaders of the C.U.P. always tried to run Pan-Islamism and Pan-Turkism in double harness. It is only since the rise of a new Turkish national movement in 1919, under the stimulus of the Greek invasion of Anatolia, that the leaders of Turkey have consciously and completely abandoned the Islamic basis of the Turkish state, and have constructed a Turkish Republic on exclusively national foundations. Meanwhile, Mustafa Kemal Pasha and his party, that is, the very Turks who have brought Turkish nationalism to maturity, have thrown over the other side of the original movement, which insisted, not merely upon Turkifying the Ottoman state, but on re-creating the links between the Ottoman Turks and other Turkish peoples.

This latter movement, to which the name of Pan-Turanianism,

in the sense of Pan-Turkism, properly belongs, resembled the wider Pan-Turanianism of the Hungarians in having a predominantly political complexion. From the political point of view the essential fact about the present distribution of the Turkish-speaking peoples as a whole is that nearly two-thirds of them (reckoning by aggregate population) live under Russian government, while less than one-third live in Turkey itself. Thus, before the Russian revolution of 1917, when the Russian Empire was Turkey's principal enemy, the promotion of a Pan-Turanian movement among the Tsar's Turkish-speaking subjects seemed to Turkish statesmen of the Union and Progress party a powerful means of weakening and possibly breaking up the Russian Empire.

On the other hand, after the revolution of 1917, Russia suddenly changed from being Turkey's principal enemy to being her principal ally, and the new Turkish nationalists, in their life-and-death struggle with Greece and the principal Allied Powers, naturally abandoned a movement which would have made friendly co-operation between the new Turkish Republic and the new Russian Soviet Union impossible. Moreover, the Union of Socialist Soviet Republics, while losing vast territories which had belonged to the old Russian Empire on its European border, succeeded in establishing its sovereignty *de facto* over all former Russian territories in Asia, that is, over all former Russian territories containing Turkish-speaking populations. Thus the expected break-up of the Russian Empire did not take place as far as its Turkish-speaking subjects were concerned; and, for these several reasons, the Pan-Turanian movement, after obtaining a certain notoriety during the years 1914-7, has sunk into an obscurity from which it is unlikely to emerge, at any rate in its previous form.

It is to be noted, however, that the 15,000,000 or 16,000,000 Turks of the Union of Socialist Soviet Republics have been given a far-reaching political autonomy within the framework of the Union, which they never enjoyed under the Tsardom. Of the six republics constituting the Union two, namely the Turkmen and the Uzbek Republic, are Turkish. Again, one of the three members of the Trans-Caucasian Republic (which itself is a member of the Union) is the Turkish Republic of Azerbaijan. Finally, within the Russian Socialist Federal Soviet Republic, which is the leading member of the Soviet Union, there are a number of autonomous Turkish units, such as the Tatar Republic, the Bashkir Republic, the Kirghiz Republic, the Karakalpak autonomous district, and several other less important territories like the Yakutsk Republic in the far northeast of Siberia. Thus in the constitution of the U.S.S.R. the germs of a new Pan-Turanian movement are latent. (See TURKEY.)

**PAPACY** (see 20.689).—The year 1910 found Pius X. restoring the evangelical framework of the Church. After the break with France his tendency lay toward devotion, not politics. The visit of President Loubet to Rome led to the withdrawal of the French Embassy because, France being in diplomatic relations with the Papacy, President Loubet ranked technically as a Catholic Sovereign and broke the Papal Decree concerning official visits to the Italian King. A Protestant King under the same circumstances could be made welcome at the Vatican. The visit of President Roosevelt was a lost opportunity; friction was engineered by interested parties. The only Catholic Sovereign who visited Rome was the Prince of Monaco in the guise of a lecturer. With the French and Portuguese Republics Pius waged open war. He declined all compromises with French law, while the persecution in Portugal evoked the Encyclical *Jam dudum in Lusitania*. Decrees as purely ecclesiastical as the *Ne Temere*, defining the conditions of Catholic matrimony, or that regulating the anti-Modernist oath, roused protest, principally in Germany. Both were directed against bad Catholics. For Protestants in good faith he maintained absolute toleration. The Pope sometimes seemed to see Modernism in an exaggerated light, for he

pressed safeguarding measures upon dioceses innocent or ignorant of modern thought. Pius had decided that Modernism was Pantheism, and insisted on destruction before discussion; but by a letter to the Bishop of Limerick, he approved Newman's works; and under the cloak of Newman all modern thought, not demanding conclusions against tradition, finds honourable harbour. The Encyclical *Pascendi gregis* cut a few self-engineered Modernists from the Church, like Loisy and Tyrrell. Pius gave no quarter, and a great many loyal writers and thinkers were hermetically sealed in their own minds. It proved a sound caulking of the Ark, but original exegesis disappeared with the exception of scholars like the Dominican Lagrange, who was protected by his Order against the standards of Rigorism. The Encyclical *Editee saepe* on St. Charles Borromeo was thought to insult German history and the Princes of the Reformation and received modifications. The Modernists had attempted to rationalise a Creed whose value and distinction lay in opposing a Damascus-blind Faith to the earthly working of Reason. Pius minded less the Socialist tinge in the German Centre party than the Modernist colour in German professors. He disliked the Catholic Centre simply because it was political, but he made no decision between Cardinals Kopp and Fischer concerning Christian trade unions.

He did not approve a Catholic party in Italy under a Modernist and Socialist leader like Don Murri, against whom Catholic action was organised by lifting the *Non-expedit* of his predecessors whenever the Pope could help Conservatism to defeat Socialism. On one principle he supported the Italian Govt., which he protested against on another. By allowing Catholics to vote at times, he outvoted Divorce Law and drew personally closer to Italy. The insults offered him in Rome were due rather to a clique than to the people, who felt that he was Italian at heart. He blessed the Italian tricolor among the symbols of Catholic societies, but he protested bitterly against the statue of Giordano Bruno and the speech of the Mayor Nathan. He was not political except in his measures to bring the Italian Catholic party and the French Sillonists under episcopal control. Pius not only trimmed but discarded modern philosophy and politics. His reforms in discipline and devotion installed new disciplinary engines. The diplomatic web woven by Leo XIII. and the political entanglement bequeathed by Pius IX. were swept aside by an unrelenting desire to reform not only the universal machine and the text-books of the Church, but to regulate the writings and thought of individual Catholics. However expedient a council, the Pope proved more effective.

He founded the Biblical Institute based on the Bible, the whole Bible and nothing but the strictest interpretation of the Bible by the Church. Pius accepted and demanded belief in a verbal inspiration of Scripture, though by entrusting a revision of the Latin text to the Benedictines he admitted scribal error in the Vulgate. Degrees in Scripture were granted after serious and searching examination. Ineffective seminaries were suppressed and reluctant Bishops were deposed. Idle priests were banished from Rome. Rome herself received vigorous visitation after three-quarters of a century. Pius introduced a uniform Catechism into Italy and appointed a Commission to codify the canon law. He required a restoration of true Church music. He introduced frequent and juvenile Communion, thus quenching the embers of Jansenism. He by the *Sapienter consilio* reformed the Roman Curia. By the *Commissum nobis* he had abolished the veto of Austria or Spain in future conclaves, and buried future procedure in strict secrecy. He simplified the religious orders, establishing, for instance, the Franciscan Union. He upset the theory of Cardinalial posts and demanded merit alone for the Sacred College. To the application for Red Hats he grimly replied that he was a tailor (*Sarto*), not a Hatter!

By the Decree *Divino afflatu* Pius reformed the Roman Breviary, so that the Psalter came more truly to be said weekly. The accumulation of Feasts was checked, and holidays of obligation were practically reduced to eight in the year, apart from Sundays. The Divine Office was lightened and the Breviary abbreviated, making it a way rather than a maze of devotion. He developed the Eucharistic Congress, sending Cardinal

Legates to various countries. He interested the United States by creating two American Cardinals. France he soothed by beati-fying Joan of Arc and kissing the French Tricolor in the presence of 67 French Bishops. He was an evangelical Hildebrand and liable to the impulses and utterances of a saint.

To Britain Pius was propitious. He sent his *legatus a latere*, Vanutelli, to London for the Eucharistic Congress of 1908. He removed Britain from the care of Propaganda to the general law of the Church and created the new Archdioceses of Liverpool and Birmingham. He sent an Apostolic Delegate, Ceretti, to Australia and raised two Englishmen, Bourne and Gasquet, to the Sacred College. In 1913 he celebrated by the Encyclical *Magni faustique* the 16th centenary of the Peace of Constantine. Throughout 1914 he foresaw war and uttered warning of days "when class is rising against class and nation against nation." To his Secretary, Merry Del Val, he said prophetically: "We shall not pass the fourteen." The War overwhelmed him and he died the day the Germans entered Brussels. A legend was spread that his warning letter to the Austrian Emperor was withheld. The truth was that the Emperor asked for his blessing and the Pope replied that he blessed Peace—not War.

#### ELECTION OF BENEDICT XV.

The disorganisation of Europe did not prevent the Cardinals meeting. The policy of Pius X. was upheld by the group around Cardinal Serafini, while the moderate group round Cardinal Maffi coalesced with those who desired a diplomatic Pope, and elected Cardinal Della Chiesa, who took the name of Benedict XV. The election of Benedict was humanly unforeseen. He had been appointed to Bologna to suppress Modernism, but he was left for seven years without a Red Hat, to the perplexity of historians. After 100 days' Cardinalate he was Pope! His entire Pontificate was occupied with efforts to bring peace or to assuage the effects of the War. In Nov. 1914, in the Encyclical *Ad beatissimi*, he declared mystically that the days foretold by Christ, when nation should rise against nation, had actually come to pass.

The belligerents watched for hints of approval in spite of the philanthropic neutrality. Excluded from the Conference of The Hague in 1899, the Papacy was not in a position to pronounce upon the invasion of Belgium, though any proven atrocity to nun or child would have met stern condemnation. He made the Holy See a bureau of charity rather than a court of justice. It may be said that a courteous diplomatist and an erudite lawyer went in search of peace, exploring and extolling every avenue that lent the least hope during years of world despair. Benedict was impartial to the nations, but the nations were not impartial to him. He set himself in a halo of neutrality, but he referred to "our beloved people of Belgium," and appealed to the invaders not to devastate, and to the devastated not to aggravate their own plight. He denounced "every injustice by whatever side committed," which Gasparri amplified by specifically including the invasion of Belgium, and the Pope wrote Cardinal Mercier the words, "Your cause is our cause." At the same time he complained of the treatment of Catholics by the Russian Army in Galicia. Though the Holy See set great store on diplomatic action, that action tended to disappointment, whereas the strictly religious policy brought a growing prestige and success.

In 1914 Sir Edward Grey sent Sir Henry Howard, followed in 1916 by Count de Salis, to reopen English relations, which had officially lapsed since the reign of Queen Elizabeth. The Apostolic Delegate at Constantinople was able to arrange for the exchange of British prisoners and the care of British graves in the Dardanelles. At Constantinople Benedict received the tribute of a statue erected by all communities in recognition of his efforts to save nations from each other.

The Pope's war efforts may be set under:

- (1) The exchange of prisoners unfit for further military service.
- (2) Liberation and exchange of detained civilians.
- (3) Hospital treatment for sick and wounded.
- (4) Sunday rest for prisoners of war.

The Vatican acted, but not strenuously, when Bethmann Hollweg proposed a German peace at the end of 1916. Cardinal Gasparri urged Mr. Balfour not to give a flat refusal, for the sake of neutral opinion. If the Germans were called to state their terms, the terms might be moderate, and, if they were not, the moral advantage would lie with the Allies. The Pope told de Salis that the moment did not appear suitable for making suggestions to the belligerents.

At the beginning of his reign the political force of the Vatican was nearly nil. Without achieving spectacular success, Benedict spread conviction that his was a force with which it was advisable to be on terms of approach rather than of reproach, provided that distinction was made between internal ecclesiastical policy and the outside policy. Benedict's outside policy remained a tenacious demand for peace. He proposed a conference of belligerents on the basis of "eliminating unjust and impossible pretensions." When Italy entered the War, he blessed the Italian priests called to serve, while remaining in touch with the Austrian Government. With the narrowing of communications, the Pope complained that "complete and precise judgment on events" was impossible. In the dangers of Universal War the Holy See inclined to be indulgent, if not changeful. The unwritten alliance of the Italian and Papal Govts. was a sign of Benedict's times to be consummated by his successors.

With the entry of Italy a secret pact was made under Sonnino by which the Allies excluded the Pope from discussion of the Peace. This was published in 1917 by the Bolshevik Government. The German and Austrian representatives to the Vatican withdrew to Lugano, but Italy respected Papal communications with enemy countries in spite of the averted suspicion of pro-Austrianism. The disaster of Caporetto was met at the Vatican and the Quirinal by mutual forbearance and succour. The Pope declared that he looked to solve the Roman problem not by foreign arms but by the Italian sentiment of justice.

Still the Pope remained neutral, sharing with President Wilson the hope of a negotiated peace. The Vatican Council had been suspended before it could deal with practices of warfare. The Church therefore could only offer generalities without pronouncing on clear cases. After the sinking of the "Lusitania" the Pope protested against "methods of attack contrary to the laws of humanity both by land and sea." The transportation of Belgians and the bombing of undefended cities were condemned, but the Pope was unheard and increasingly criticised by both sides.

Benedict passed from exhortation to warning. It culminated in his supreme but unsuccessful bid for peace by the Note of Aug. 1917, when he asked with ironical despair, "Must the civilised world be reduced to a graveyard?" Austria was anxious for peace, but Germany offered no data. The Nuncio Pacelli sounded the German Govt. in June. Bethmann Hollweg had begun to show himself sympathetic even on Belgium and Alsace-Lorraine. In Aug. the Peace Note was distributed. By a curious irony, George V. was asked to give copies to the French and American Presidents and to the King of Italy. The Note caused no small stir, but it was ignored by the Allies and refused by Germany. The Pope claimed impartiality, pleaded for disarmament and arbitration, stigmatised the War as "useless massacre," since both sides recognised that "the honour of arms is safe." He proposed the evacuation of Belgium and invaded France and the return of the German Colonies. He added a plea for the small States. Ludendorff called him a French Pope and Clemenceau a German one.

The German Chancellor Michaelis was more hostile than the Allies, to whom he left the reproof in the declarations of Wilson and Lloyd George. Fundamentally there was no difference between the Pope and the Allies, except as between a negotiated and a dictated peace. The Note represented the measure of European exhaustion had not the United States entered the War. The Vatican, though represented unofficially at Washington, had no means of expecting either Wilson's declaration of war or peace. Benedict issued an Encyclical concerning the future, whereas the Pope's terms were a Protocol based on the past. Wilson's reply hushed the Pope, who, deeply

disappointed returned to the alleviation of the victims. His contrast will always lie with Wilson. For nearly three years they personified the greatest spiritual neutrality and the greatest temporal neutrality in the world. The Pope, more tenacious and consistent, was left alone in his plea for a just and durable peace to the profit of neither side. His consistence was twice impugned by interviewers and by the treason of Mgr. Gerlach, who helped the enemy of Italy actively while himself sheltered in the Vatican and was handed over to the Italians by Vatican officials at the Bronze Gates.

Benedict in 1915 warned the Rulers, saying, "Remember that nations do not die: humbled and oppressed, they chafe under the yoke. Why not from this moment weigh with serene minds the rights and lawful aspirations of the peoples?" It was two years before Wilson, converted, was chastising the Teutonic Powers with the same admonition. The Pope did not include the Temporal Power of the Holy See among unredeemed aspirations. He reduced an irreducible claim to Sovereignty to an appeal to help the Holy See out of a false position. Though Benedict was puzzled by Wilson's *volte-face*, he realised that it was Michaelis who brought his Peace Note to nought. The Erzberger revelations showed that the Pope was not met in Germany on the Belgian question with as much good will as was shown by the Allies. Though the peace declarations of Wilson and Lloyd George showed modelling on the Pope's Peace Note, the Pope after 1918 became restrained. With the collapse of the Central Powers he accepted "all legitimate changes in politics and territories."

Neutral in the War, the Pope was left neutral in the Peace. That Benedict had no share in the Treaty of Versailles proved a blessing to the Vatican and was consistent with the policy which maintained that the Pope would take no part in any peace dictated by Germany or the Allies. The Vatican sincerely believed that only by agreement was peace possible. At Versailles the Pope's unofficial representative, Ceretti, was supported by England in obtaining modifications in favour of Foreign Missions.

Of the Treaty of Versailles, the Pope showed implicit blame and justified suspicion as long as it failed of Christian bases. The Pope seemed almost, like Cato, to favour the vanquished because they were vanquished. The Germans, who had not been sympathetic to the Vatican during the War, looked to the Pope for help to avert the worst consequences of the Peace. By the Encyclical *Dei Munus* of 1920 the Pope called for European reconciliation rather as a Christian family than as a mere League of Nations. In the same year he celebrated the memory of St. Jerome by the Encyclical *Spiritus Paraclitis*. By 1921 he celebrated the seventh centenary of St. Francis in the *Sacra propediem* and the eighth of Dante by the *In praeclara summorum*. His utterances returned to the greatness of the Catholic past. Though a disappointed diplomatist, he never relaxed his impartial benevolence. His relations with Italy became so friendly that he relaxed the conditions laid down for the visits of Catholic Sovereigns to Rome, opening the way for visits from the Kings of Spain and Belgium. He received the ruling American President and the Prince of Wales. Like Leo XIII., whose pupil rather than whose equal he was, Benedict had been inclined to sacrifice Irish and Polish political aspirations to the importance of British and Russian friendship. After the Russian revolution he was quick to recognise the Polish Republic and to nominate a Polish cardinal. He would not declare himself during the War between the complaints of the Irish Bishops and the British Govt., but after the Peace he demanded an Irish settlement and beatified Oliver Plunkett.

Though France had prevented the Holy See obtaining direct access to the Chinese Govt. instead of using the French Minister, she found it no longer dignified to use the back stairs and sent her own Ambassador to the Vatican. When Benedict succeeded, there were two Embassies and twelve Legations. He left his successor with seven Embassies and eighteen Legations.

One stupendous intellectual achievement crowned his War-harassed reign, the issue of the new Codex of Canon Law, edited by order of Pius X. and promulgated by Benedict under Cardinal Gasparri's supervision by the Bull *Providentissima Mater* in

1917. The original Commission of five Cardinals appointed in 1904 had died and been succeeded by eight others, who achieved the gigantic work of codifying the Canon Law of centuries under 2,414 Canons, the most astounding legal *tour de force* ever accomplished.

Early in 1922 Benedict died suddenly. Until his archives are published his career cannot be appreciated historically, but upon his catafalque the Church, which he had served in agonising days, inscribed his *epitaphia* thus:

1. Vainly he tried by his counsels of a Christian peace to put out or restrain the fire lit by the greatest of wars. He succeeded by all means in making it less calamitous.

2. He made opportune prescriptions for the diffusion of the Catholic Faith. He excited the zeal of the better to help the heralds of the Gospel by prayer, by alms, by action.

3. The authority of the Apostolic See rising to the ascendant in public opinion, he brought almost all States to seek bonds of amity with the Church.

4. Admirably incarnating the charity of Jesus Christ, he clasped with paternal heat all the miseries of the people and comforted them by the effusion of his kindness.

#### ELECTION OF PIUS XI.

The Cardinals elected Cardinal Ratti, Archbishop of Milan, as Pope, under the title of Pius XI. The secrecy of the Conclave was well kept, but it was obvious that neither the Rigidist school of Pius X. nor the diplomatic policy of Benedict would be carried on, though by continuing Cardinal Gasparri as Secretary of State the new Pope created a precedent. His first act was a *beau geste* toward Italy, for he gave the long withheld blessing of Orb and Urb to the saluting troops of the Italian Kingdom. From that moment the Roman Question could be described as in final solution. No Pope of modern times has been so universally hailed by a broken world or received such an international endorsement. His first regret was that the American Cardinals had arrived too late, and he extended the interval between a Pope's death and the Conclave to 15 days. His life had been passed in the Ambrosian and Vatican Libraries, with Alpine holidays. Interesting were such incidents as his Latin speech in Oxford at the celebrations of Roger Bacon, and his ascent of Monte Rosa. He has never been happier than when issuing Encyclicals on great scholars like St. Thomas Aquinas and St. Francis de Sales, whom he made patron of Catholic journalists. His Encyclical *Ubi Arcano Dei* was a signal for charitable rather than diplomatic action. The absence of Italy from the nations attached by bonds of friendship to the Holy See was lamented. The alliance of the Vatican and the Fascist Govt. has been indubitable, though the Pope has declared that Divine Providence has not yet indicated, nor human wisdom discovered, a substitute for the old Temporal Power. The new conception of the Papacy as one of the glories of the Italian Kingdom has been almost embarrassing to the Vatican, which has refused to condone outrages committed by Fascists.

Naturally, the conquered States flocked to the protection and internationalisation afforded by the Church. On the Ruhr question the Pope pointed out a possible equilibrium between charity to Germany and justice to France that France herself could not dispute. Such phenomena as German and French Embassies at the Vatican signified both the measure of German defeat and of French satisfaction. During 1925 the Pope celebrated a Holy Year of Jubilee, and by receiving nearly 200,000 pilgrims in Rome enabled many threads to be laid for the healing of the nations.

Pius XI. has remained on religious territory, making no effort to be included or consulted by the Powers except when ecclesiastical interests are at stake—the Holy Places, for instance. At first the Vatican welcomed the British Mandate in Palestine preferring a sympathetic non-Catholic power in the East to an anti-clerical protector like France. But the progress and priority of Zionism mortified Catholicism exceedingly, and the Holy See turned for assistance to the League of Nations. The Orient has been the scene of great activity by the Holy See. For centuries

the Czar and the Caliph had been inexorable enemies of the Vatican. With their disappearance the new Pope made instant advances. The Encyclical *Ecclesiam Dei* on the third centenary of St. Josaphat was an appeal to the Slavs. The cause of Oriental unity with the West became the Pope's prepossessing desire. Missions were dispatched to Russia. The Pope called Latin attention to the splendour of the Slavic rite; and to the Conference at Geneva expressed Russian sympathies. With some difficulty the Pope obtained from Lenin the release of an Archbishop from death. Nor was the Pope's protest against the spoliation of the Orthodox Church listened to. But the most striking ecclesiastical result of the War has been the opening of Oriental Europe to the Latin Church. The Papacy undoubtedly looks forward to a period of missionary activity in the East as great as that which followed the European convulsion of the 16th century. (See also ROMAN CATHOLIC CHURCH.)

Wood, articles in *The Dublin Review* (1922-6). (S. L.\*)

**PAPER MAKING** (see 20.727).—The production of paper increases *pari passu* with population: in the period under review (1910-26) the industry has grown and there has been marked progress in scientific-technical control of its operations.

The evidence of this development is the record in the form of periodical publications of the research work of chemists and engineers engaged in the industry, evoked and stimulated by the technical societies founded in all the leading countries of civilised activity. In Great Britain the Paper Makers' Association has constituted a technical section which publishes its "proceedings"; in France a school of instruction and research has been founded at Grenoble; in Germany the "Verein der Papier Techniker" has contributed important advances, and its technical publications have taken a leading position; in America the Government Forestry Department has carried out elaborate researches, especially in the study of fibrous raw materials; in Canada likewise the Forest Products Laboratories (Montreal) have worked in a systematic programme which has now resulted in the constitution of a department of the University devoted to cellulose, paper making and the related industries. Notwithstanding this activity in the investigation of the first principles of the Art, the period is not marked by any outstanding feature of scientific or technical novelty.

**Beating Processes.**—The beater and beating process are the most important factors of paper mill production. The old form and type of beating engine known as the Hollander not only survives, but is still found the most efficient machine for the preparation of fibrous raw material for important classes of paper in competition with the elaborated modifications which have resulted from the endeavours of engineers to improve a machine recognised to be wasteful of power.

The beating process is one of the most complex in manufacturing industry. The beater was first designed for the treatment of wastes from the textile and rope-twine spinning industries, and substitutes a continuous process for the medieval methods of reducing these wastes to "pulp" by stamping or wet-grinding. In treating rags, cuttings and twisted wastes the beater undoes the work of the spinner and weaver, opening out the component fibres for the further reduction, operated by the special mechanism of the beater roll, carrying its battery of knives or bars, running at high speed over a corresponding provision of bars in the bed plate of the circulating trough.

There is in this work a further complex of results or effects—(1) a cutting of the fibres, *i.e.*, reduction of length, (2) a splitting or shredding of the fibres in the length of their axis, to fragments, fibrillae of less diameter, (3) an effect known integrally as "hydration" by which the water is beaten into the fibre substance in such way as to facilitate its suspension in the carrying water,

at the high dilution required for running on the wire of the paper machine. In modern paper making the beater preparation is applied to raw materials which are already in the form of ultimate component fibres—"half stuffs," as a result of previous chemical treatment of the actual raw or original material, *e.g.*, wood, straw, esparto grass. For measurement of the work of the beater, in the exact terms of "efficiency," this is already a simplification, and it becomes possible to equate the expression for consumption of power to certain of the above effects which can be measured.

**Scientific Analysis.**—This is the basis of the mathematical treatment of the subject up to the time of S. Smith's treatise. In this treatise, which embodies several original methods of experimental investigation, the author separates and separately measures (a) the cutting action from (b) the crushing action of the roll-bar bed-plate contacts. In regard to the effects of internal friction of the stuff or pulp surfaces, he formulates a "law" in new terms, *viz.*, that resistance to displacement along a surface or plane of the pulp or wet stuff, is proportional to the surface dimensions and independent of pressure and speed of movement. Lastly he discusses the phenomenon which must be the immediate factor of the specific beating effects, that is the attachment of fibre to the beater bars rotating in the pulp mass and thereby brought into contact with the bars of the bed plate; as a contribution to this factor he especially treats the invisible phenomena of the beater bar cells or spaces between the bars, which are filled with the pulp mass and which is necessarily in a state of rapid rotation before and during the contact. This physical mechanical effect has certainly been overlooked in previous treatises, and the author is justified in claiming attention to it and in basing certain improvements of beater construction upon its recognition. For the attachment of the fibres in this sense the English Edition adopts the expression "fibrage" which is convenient and self-explanatory.

#### RAW MATERIALS

The addition of the wood pulps—cellulose (*q.v.*) as well as ground woods or "mechanical" pulps to the paper makers' supplies of raw fibrous materials, in the last century (1880-90) led to much unmethodical and indeed reckless treatment of the forest supplies of original material. Under methodical reafforestation (see FORESTRY) equilibrium has been reached in certain countries and a continuous supply of maturing timber guaranteed. But in view of the world's rapidly increasing consumption the question of a limit of supply is raised: and alternatively the question of supply of crop material in adequate massive quantity.

**Cotton Residues.**—In the cotton crop and the residues of lint and short fibres remaining attached to the seed after removal of the textile cotton, there is an immense potential supply of fibre, *e.g.*, on the United States production of seed alone, estimated at 300,000 tons. A de-linting machine invented by E. de Segundo has demonstrated its efficiency, and the "de-lint" is produced in Great Britain by the Cotton Products Co. in a condition of cellulose concentration or content as high as 70-80%. The matter appears to have passed into a phase of arrested development in encountering difficulties beyond the technical, which it is stated, have been surmounted, and it still offers the prospect of a most important and desirable addition to our supplies (see *Journal R. Soc. of Arts*, 67, 1919, pp. 184-202).

**Flax Straw.**—Another crop material largely unutilised is the flax straw or stem of the plant from which the seed (linseed) has been removed. This waste represents an enormous tonnage and loss of its 15-20% of fibre (Cellulose) of excellent paper-making quality. There have been several attempts to realise this potential industrial value, but with no further result than to fully demonstrate the practicability of a well organised scheme.

**Bamboo.**—Bamboo again, which is a massive growth and may be worked as a crop, has been the subject of much investigation which has resulted in industrial developments for the production of pulp. This matter also has reached a phase of arrested development.

*Papyrus*.—Perhaps the most massive of the vegetable growths of the world is the papyrus of the Nile and other African rivers. The fibro-vascular bundles of the relatively massive stems of the Papyrus break down under ordinary chemical treatment to a complex of fibres which have paper-making quality of the highest order. In several cases bulk quantities of this reed-material have been treated in English mills and worked up to papers of quite exceptional characteristics. These, however, represent merely attempts without industrial issue. Operations carried out in the Sudan (Sudd Fuel Co.) and in Zululand (Walmer Papyrus Co.) have ended in failure. In the latter case, the equipment of a factory for "half stuff" and "quarter stuff" production was carried out on modern design; but the venture failed for other than technical reasons.

The above represent potential supplies of sufficient magnitude to affect the world's markets in raw materials. The failure to develop them industrially illustrates the exacting character of the specification of qualities and conditions to be fulfilled for acceptance among the staple raw materials of this industry. The failure in these cases is in respect of conditions rather than qualities, and the matters may be regarded as open for more mature consideration and effective handling.

*Processes*.—The separation of cellulose from non-cellulose by treatment of fibrous vegetable material with alkaline lye, the general method (a) is a chemical process of great complexity. By contrast there are two methods of resolving these plant structures by chemical treatment with electronegative reagents, viz.: (b) sulphurous acid (c) elementary chlorine, which depend upon a simple quantitative reaction of synthesis with their lignone components, the main constituent of the non-cellulose admixtures, which convert these to derivatives freely soluble and easily removed.

(a) W. Raitt has devised methods of fractional treatment for removal of the non-cellulose components of raw materials which are described in his reports on "Bamboo and Indian Savannah Grasses," *Indian Forestry Records*, 1912-3, and invented a special digester for the working of the processes (English Patent 16488-1915).

This leads to a notable simplification of the reactions with the alkalis employed and in consequence produces a cellulose pulp of much improved colour, and economy in the consumption of alkali.

(b) Sulphurous acid combined in the form of a bisulphite of lime, magnesia, soda, is the reagent employed in the industrial process for obtaining wood cellulose. The process has developed from its small beginnings in 1880 to the immense industry of the present time without a clear recognition of the actual chemistry of the process. Recent investigations have now established that the process depends upon direct synthetic reaction of sulphurous acid with the lignone components of the woods.

A sulphurous acid process carries resolution to a limit but the addition of ammonia in small quantity completes the resolution to cellulose and gives a by-product liquor free from the salts which, in the proportion of the present process, are a serious bar to the employment of the concentrated by-product in various industries. This by-product is one of the colossal wastes of the industrial world amounting to millions of tons per annum, and therefore it is obviously one of the most serious objectives of the chemist to convert this waste to value. See *J. Soc. Chem. Ind.*, 1924-5, papers by C. F. Cross and A. Engelstad (2) and by C. Doree and L. Hall (2).

(c) The process of isolating cellulose quantitatively by treatment of prepared vegetable tissue with chlorine gas was brought into prominence by Cross & Bevan in 1880-5, and since adopted as the standard laboratory method. A French chemist-engineer, De Vains, has invented and devised a comprehensive scheme with its several parts for realising this treatment as an industrial economic process. Factories have been established and are working on a large scale in France, Belgium, Canada and the Far East; results obtained especially with esparto and the cereal straws confirm the inventor's anticipations in regard to economy and certainly yield as might be expected a cellulose pulp of higher quality than by the relatively uncontrolled caustic alkali processes. The process is the subject of descriptive papers by J. Strachan in *The Paper Trade Review*, 1923-4.

Sutermeister, *Chemistry of Pulp and Paper Making* (1920); *The Manufacture of Pulp and Paper*, prepared under the direction of the Joint Executive Committee on Vocational Education, N.Y. (5 vol., 1921-5); Sigurd Smith, *The Action of the Beater*, Paper Makers' Association of Great Britain (1925); G. Clapperton, *Practical Paper Making*, 3rd. ed. (1926). (C. F. C.)

**PAPINI, GIOVANNI** (1881— ), Italian author, was born in Florence Jan. 9 1881, and took to literature at an early age. He

contributed to many reviews and founded two new ones, *Leonardo* (1902) and *Lacerba* (1913) and was also joint editor of *La Voce* in 1912, at a time when that journal gathered around it many of the most brilliant and original young Italian writers of the day. He was professedly an iconoclast, and in a volume entitled *Stroncuture* (1917) he demolished many established reputations. Among his many works are several volumes of essays and criticism—*La paga del Sabato*, *L'uomo Carducci* (1918), *Il crepuscolo dei filosofi* (1906), and two novels *Un uomo finito* (1922) and *Parole e Sangue* (1921). His poetical output includes *Cento pagine di poesia* (1920), *Opera prima*, *Giorni di festa* (1920). Subsequently he surprised his readers by casting off his caustically sceptical and critical attitude and evolving into a mystic, with his *Storia di Cristo* (1921), a book which achieved immense success throughout Italy and abroad.

See E. Fabri, *Papini come scrittore* (1921) and R. Fondi, *Un Contributo: Papini* (1922).

**PAPUA** (see BRITISH NEW GUINEA, 19.489), a Territory of the Australian Commonwealth. The area, including surrounding islands, is 90,540 sq. miles. Papua occupies that part of New Guinea lying between the extreme limits of 5° and 12° S. and 141° and 155° East. The white population in 1924 numbered 1,276 and the estimated native population 275,000.

*Production*.—The physical features of Papua are favourable to agriculture. Rich soils at varying elevations, and heavy and evenly distributed rainfall, have ensured success in the cultivation of almost every tropical product. The system of land tenure is leasehold; no freehold is granted. The Government buys from the natives and leases to planters. The area held by the Crown in 1924 was 800,712 ac.; the area held under lease was 190,124 ac., as compared with 218,950 ac. in 1919 and 290,936 ac. in 1913. In 1913 there were 216 plantations, principally coconut, with a total area of 35,363 acres. In 1923 the plantations numbered 260, area 60,863 ac.; 46,798 ac. were under coconuts, 7,481 ac. under rubber, and 5,849 ac. under hemp, while other tropical products such as cotton, rice, coffee, tea, cacao, vanilla, tobacco and cinnamon were also grown. In 1924, 7,315 tons of copra and 304 tons of rubber were produced. It was estimated in 1917 that over £1,000,000 had been expended in plantations. An Act was passed early in 1926 by the Commonwealth Govt. granting bounties on the production of certain Papuan products, and at the same time a tariff preference was granted to these products imported into Australia. In Sept. 1925 the coastal provisions of the Australian Navigation Act, in so far as they were applicable to the Territory of Papua, were suspended.

*Minerals*.—Minerals have been found over a wide range of country, and include copper, gold, tin, lead, zinc and osmiridium. The yield of gold in 1923-4, valued at £6,702 was the lowest recorded since 1895; in 1921-2 the value was £68,726. In 1924 the first copper smelters were erected. The ore reserves were then estimated at 290,000 tons containing 13,300 tons of copper and 36,250 oz. of gold. The existence of petroleum has also been traced. Exploitation of the oil-fields by private individuals or companies was not permitted before 1923. Pearl-shell fishing is important: in 1923-4, £6,120 worth of pearl and trochus shell were exported, but returns are mostly credited to Queensland whose boundary comes within a few miles of the Papuan coast.

*Native Labour*.—The supply of native labour presents considerable difficulties. The population is scanty and the natives are peasant proprietors with land of their own sufficient to supply their simple wants. Under the Native Labour Ordinances the rights of both employer and employee are preserved. Service on the part of the native is voluntary and he must be justly treated and properly fed. Employers may recruit personally or obtain their natives through a licensed recruiter. The number engaged under contract of service during the year ended June 30 1924, was 7,578. Under the Native Taxes Ordinance, 1918, a tax not exceeding £1 may be imposed on natives. The proceeds of tax must be expended on education or on purposes directly benefiting the natives. The taxes collected in 1923-4 totalled £16,410. The revenue in 1923-4 amounted to £77,150, exclusive of the

Commonwealth Govt. grant of £50,000 per annum, and the expenditure £131,640.

Most of the plantations are close to the coast, and communication is by sea. There are some 240 m. of roads. Port Moresby is the seat of government and chief port. A three-weekly steamship service, subsidised by the Commonwealth Govt. for the carriage of mails, is in operation between Port Moresby, Samarai and Sydney. (See AUSTRALIA.)

**PARACHUTES.**—In 1924 parachutes were recognised as a part of the standard flying equipment for use with aeroplanes. The use of parachutes with large, dirigible airships is usually optional, the crews of such craft often preferring to run risks

without them to the trouble of carrying them strapped to their bodies. The development of a parachute that could be used in aeroplanes was inevitable. As flying increased, so did accidents. When an aeroplane is disabled in the air through collision, fire or failure of the control cables, an aviator can seldom save himself except by parachute.

During the last days of the World War in 1918, German aviators jumped from their machines when the gas tanks were set on fire or the controls cut in combat, but after the War little was done to complete the use of parachutes until about the year 1921. At this time British and American aviators began working upon a parachute that could be carried conveniently by a pilot. It was obvious that the old style balloon parachutes were too cumbersome to carry in aeroplanes. In 1923 the U.S. Army Air Service developed a seat pack type parachute that was

generally recognised the following year as standard and practically 100% efficient. More than 1,500 experimental jumps were made in achieving perfection.

**The Standard Parachute.**—The standard aeroplane parachute is folded into a compact pack about the size of an ordinary chair cushion, but about twice as thick. It is worn strapped upon the body with the pack in place beneath the buttock of the wearer and it becomes the cushion when the aviator takes his seat in an aeroplane. Thus, the regular cushion in aeroplane cockpits is generally omitted. The pack weighs approximately 18 pounds. It is made of carefully chosen untreated silk; the untreated silk is used because it does not become creased so easily as the finished material. When open, the parachute is 24 ft. in diameter. The shroud lines are made from high-grade thrown silk and consist of not less than 32 threads of 3-ply, each with a breaking strength of not less than 400 pounds. The main parachute is pulled from its case by a smaller "pilot chute," about 3 ft. in diameter, which operates by spring when the aviator pulls the "rip cord" that holds the pack closed. In jumping from aeroplanes, aviators do not pull the rip cord immediately, but wait two or three seconds until clear of the machine. The parachute descends at the rate of 16 to 20 ft. per sec., depending upon the weight of the wearer and density

of the air. This is equivalent to jumping from a height of 7 ft. without a parachute. Each parachute is tested to withstand an operation of 200 lb., falling at the rate of 400 m. an hour.

The lowest height at which a parachute will open is probably not less than 150 ft., although a few forced jumps have been

FIG. 2.—A normal parachute jump.

made at slightly lower altitudes. The lowest altitude considered safe is 250 ft., although the higher the jumper is, the better are his chances, because sometimes delayed openings occur. Jumps have been made from aeroplanes as high as 25,000 feet. An aviator usually pulls the rip cord and releases his parachute within a few seconds after leaving an aeroplane, but openings have been purposely delayed for experimental reasons while a jumper fell for about 1,500 feet. The first parachute jump ever made from an aeroplane was made by Captain Berry near St. Louis, Mo., U.S.A., in 1912. This jump was made with an old style balloon parachute, but, as stated previously, the old types of parachutes were too hazardous for

FIG. 3.—A normal parachute landing.

aeroplane use and very few jumps were made from aeroplanes until the development of the standard aviators' parachute.

**Parachute Flare.**—A parachute flare contains illuminating chemicals attached to a small parachute, which, when ignited and dropped from an aircraft, will descend slowly and light up the country side for many miles. Parachute flares are used for military purposes to discover night movements of enemy troops by aerial observers; by aviators to locate landing fields at night and guide the approach to the earth and to take night photographs. (C. McD.)

**PARAGUAY** (see 20,756), a republic of South America and a member of the League of Nations. Its area is 161,000 sq. m., and in addition the disputed Chaco territory covers an area of about 100,000 square miles. The estimated population (1925) is 1,000,000, in addition to about 50,000 Guaraní and Chaco Indians.

Estimated population of Asunción, the capital, in 1925 was 101,790; Villarica 30,000; Concepción 25,000. Paraguay remained neutral during the European War, but after the United States declared war on Germany the government maintained a pro-Ally attitude and dismissed some of its German employees.

**Political History.**—Dr. Manuel Gondra, inaugurated as president in Jan. 1911, held office for a very brief period. A succession of revolutions caused him to be followed by four provisional presidents whose terms of office were of the briefest: Col. Albino Jura, Jan.–July 1911; Dr. Liberato M. Rojas, July 1911–Feb. 1912; Dr. Pedro Peña, Feb.–March 1912; Dr. Emiliano González Navero, March–Aug. 1912. Dr. Eduardo Schaerer, who assumed office on Aug. 15 1912, was the first president since 1870 to complete his term of office. He was succeeded in Aug. 1916 by Dr. Manuel Franco, under whose administration Paraguay's finances attained a sound position and the meat-packing industry reached a high point of development. Dr. Franco died on June 3 1919, and the remainder of his term was filled by Dr. José P. Montero until Aug. 1920, when Manuel Gondra was elected to a second term having been elected while minister to the United States. Gondra was forced to resign in Nov. 1921 under pressure of threatened revolts. The subsequent provisional presidency of Eusebio Ayala, which was disturbed by political and personal difficulties, terminated in July 1923, when Eligio Ayala was elected president, inaugurating the most prosperous administration in the history of Paraguay. The unsatisfactory character of the world market for Paraguay's produce in 1921 had precipitated an economic crisis. The government had defaulted in payments on the foreign debt, and an American financial adviser had been called in. Under Ayala's administration the fiscal year 1924 closed with a surplus in the treasury equivalent to \$700,000, and in Sept. of that year an agreement, since scrupulously observed, was signed for the settlement of that part of the foreign debt held in London.

In 1913 direct diplomatic relations were resumed with the United States, after an interruption of eight years, and a United States minister was accredited specially to Paraguay. An extradition treaty with the United States was signed on July 30 1913.

**Education.**—Education is nominally compulsory in Paraguay, but at least 60% of the inhabitants are illiterate largely owing to lack of schools. An attempt at educational progress was made by President Franco in 1916–9. In 1919 there were 80,000 pupils enrolled on the school registers. In 1923 the total number of pupils attending the 1,204 government primary schools was 70,820; 2,089 pupils were attending the 31 private schools, and 800 the three national colleges at Asunción, Pilar and Villarica. The *Colegio Internacional*, a United States missionary institution and the largest educational establishment in Paraguay, was opened at Asunción in 1920.

**Finance.**—The budget estimates for the fiscal year 1923–4 provided for a revenue of 945,129 gold pesos and 104,488,950 paper pesos. Expenditure was estimated at 1,387,506 gold pesos and 113,534,896 paper pesos, the estimated deficit being 442,377 gold pesos and 9,045,946 paper pesos. Actual returns were, revenue 1,158,138 gold pesos and 142,346,867 paper pesos; actual expenditure was 1,232,224 gold pesos and 108,474,546 paper pesos. There was thus a deficit of 74,086 gold pesos and a surplus of 33,872,321 paper currency. The budget estimates approved for the financial year 1925–6 provided for a revenue of 1,250,330 gold pesos and 174,484,264 paper pesos. The estimated expenditure was 1,476,823 gold pesos and 164,766,277 paper pesos.

**Production and Industry.**—The cultivation of cotton is one of the growing industries of Paraguay, the quantity of ginned cotton for export having increased from 567 tons in 1922 to 2,653 tons in 1924. The expansion of cotton growing has stimulated the demand for agricultural implements. Yerba maté, or Paraguay tea, gathered in the virgin forests, is one of the chief articles of export, the quantity exported having increased from 6,908 tons in 1924 to 5,703 for the first six months of 1925. Under governmental encouragement the meat-packing and curing industry has arrived at a prosperous condition. Hides exported during the first six months of 1925 exceeded those exported for the whole year 1921. Sugar has declined, the production falling from 5,230 tons in 1920 to 2,400 tons in 1922. Tobacco reached its highest point of production in 1923 when 8,151 metric tons were exported. The chief exports in 1920 were timber and forest products \$6,581,218; agricultural products \$4,486,166; and animal products \$2,905,610. The chief imports were textiles \$3,485,714; machinery and hardware \$3,408,392; groceries and kerosene \$2,002,346. Total imports in 1923 were \$8,314,084; in 1920 \$12,724,949; and in 1910 \$6,252,480. Total exports in 1923

were \$12,097,409; in 1920 \$14,510,400 and in 1910 \$4,789,065. Imports in 1923 were chiefly from Argentina, \$2,859,520, the United Kingdom, \$1,899,609 and the United States \$1,305,897. Exports in 1923 were, chiefly to Argentina, \$9,139,326; the United States, \$1,503,311; and Uruguay, \$796,847.

**Communications.**—On Oct. 3 1913 direct rail communication was established between Asunción and Buenos Aires. This has done much to lessen the isolation of Paraguay. The Paraguay Central Railway Company has about 274 m. of track. The gauge of its main track, 232 m., was changed from 5½ ft. to 4 ft. 8½ in. in 1910 to conform to that of the Argentine railways. During the year 1923, 2,046 steam vessels of an aggregate tonnage of 221,488 tons entered the port of Asunción; during the same year 2,061 steam vessels of an aggregate tonnage of 226,020 tons were cleared from the port.

**Banking.**—On June 30 1925 a branch of the German Bank of South America (*Deutsch-Südamerikanische Bank, Aktiengesellschaft*) was opened at Asunción. A branch of the Bank of London and South America was opened early in 1920.

**PARASITOLOGY** (see 20.770).—Parasitology deals with organisms which derive their nourishment from the bodies of other organisms with which they live in varying degrees of close association and in so doing prevent them from thriving as they otherwise would do. A parasite is thus definitely harmful to its host, because it directly destroys its tissues, absorbs its fluids or excretes substances which are injurious. A malarial parasite (see *MALARIA*) lives in a red blood corpuscle from which it abstracts its food. The cell is ultimately destroyed and toxic substances and granules of pigment are liberated from the parasite. These lead to secondary changes in tissues in which the parasite does not actually live, which are as dangerous to the host as the damage directly produced. Individuals infected with *Schistosoma haematobium* (see *BILHARZIASIS*) are only slightly affected by the worms themselves but suffer very serious damage as a result of the spined eggs which work their way through the tissues toward the bladder.

Sometimes organisms, though intimately associated with others, merely feed on waste products of the body, while at other times two live together for mutual benefit. In neither instance is this parasitism. In the one the associated organism is a commensal, while in the other the two are symbionts.

**Parasites of Man.**—Parasites belong either to the vegetable or animal kingdom and may parasitise either plants or animals, but here only the parasites of man which enter into the field of medical parasitology will be considered. The vegetable parasites of man belong to the fungi, bacteria and the allied spirochaetes. Ringworm and Madura foot are caused by parasitic fungi; enteric fever, tuberculosis, leprosy (see *LEPROSY; VENEREAL DISEASES*), pneumonia and diphtheria are due to parasitic bacteria, while syphilis, yaws, and relapsing fever result from invasion of the body by spirochaetes. It is possible that the structures named Rickettsia, which occur in typhus and Rocky Mountain fever, are bacteria but at present the evidence on this point is inconclusive. In the animal kingdom the parasites of man are either unicellular Protozoa (see *PROTOZOOLOGY*) or multicellular Metazoa. To the latter belong the groups Cestoda, Trematoda, Nematoda and Arthropoda. There is also evidence that beyond the scope of the ordinary microscope there exist ultra-microscopic viruses or parasites which are responsible for disease. They are so minute that they pass through the pores of filters (see *FILTER-PASSING MICROBES*) which will not permit the passage of organisms which can be seen with the microscope. The virus of foot-and-mouth disease is of this type, while recent investigations indicate that similar organisms may be responsible for at least certain types of malignant growths. It is only possible to conjecture to which group these parasites belong.

**Dependence on Hosts.**—Parasites in general are absolutely dependent for their existence on their hosts. Except in specially

prepared artificial culture media which imitate the natural fluids in which they live, they are unable to survive in an active condition for more than a short time when separated from their hosts, though in many cases encapsulated resting stages are formed in which the parasites can live for long periods and are able to withstand adverse conditions such as desiccation and cold.

*Mode of Transference.*—If therefore any race of parasites is to survive, it or its offspring must find their way to new hosts. The transference takes place in one of two ways. Either the parasite passes directly from one host to another of the same kind (direct transmission) or it passes into an intermediate host of another kind from which it is transferred to one of the original kind. Sometimes a series of hosts is involved, as in the case of the trematode *Clonorchis sinensis* which lives in the bile ducts of man. The miracidium, hatching from the egg in water, enters a mollusc in which sporocysts and cercariae are produced. The cercariae infect carp, which lead to infection of human beings. Similarly the tape worm *Dibothriocephalus latus* requires two hosts apart from man, a copepod crustacean and a fish. The majority of tape worms which live in the human intestine require only one intermediate host.

In the case of the tape worm *Taenia solium* it is usually the pig and in *Taenia saginata* the ox. Such transmission is indirect, there being an alternation of hosts. With fungoid and bacterial parasites transmission is nearly always direct, a notable exception being *Bacillus pestis* of plague, which may have an alternative host in the flea, though direct transmission frequently occurs. If Rickettsia are bacterial organisms they constitute another exception, as they are transmitted by lice or ticks. Spirochaetal parasites are transmitted either directly from host to host, as in the case of syphilis, yaws and Weil's disease, or indirectly, as in yellow fever (see YELLOW FEVER) and relapsing fever. In the case of spirochaetes of relapsing fever a further modification occurs, for not only can the tick which feeds on an infected human transmit infection to other human beings, but it passes the infection to its own offspring, which are then able to cause the disease. This in many respects is comparable with the hereditary transmission of the spirochaete of syphilis from parent to child.

Protozoal parasites, again, are transmitted either directly through the ingestion of encysted forms, as in the transmission of the various parasitic amoebae and flagellates of the intestine and the coccidia, or indirectly, as in malaria, trypanosomiasis and probably kala azar (see KALA AZAR) and oriental sore. With the Metazoan parasites, the majority of the Cestoda and Trematoda depend on indirect transmission, though exceptionally, as in the case of the tape worm *Hymenolepis nana*, direct transmission by eggs from man to man is the rule. Both methods of transmission occur with the Nematoda. The intestinal forms pass directly from man to man by means of the eggs which escape from the intestine, while the various Filariidae, including the guinea worm, require the intervention of arthropod hosts to enable them to pass from man to man.

The round worm *Ascaris lumbricoides*, the thread worm *Enterobius vermicularis* and the whip worm *Trichuris trichurus* produce eggs which are directly ingested by another human being after they have undergone maturity outside the body in the development of an embryo within the egg shell. In the case of hookworms of the genera *Ankylostoma* (see HOOKWORM) and *Necator*, the eggs themselves are not ingested but the embryos which develop in the eggs after they escape from the body hatch in moist soil and enter the human body by penetrating the skin. Infection in the case of *Strongyloides stercoralis* takes place in a similar manner but the embryos usually hatch from the eggs before they leave the intestine.

*Filariidae.*—The Filariidae referred to above require to develop in either mosquitoes or flies of the genus Chrysops. The adult worms living in the tissues of human beings produce embryos which circulate in the blood, whence they are taken by the blood-sucking Diptera. In these flies they pass through a metamorphosis and eventually reach the proboscis. When the fly is feeding on a human being the embryos escape from the proboscis on to

the skin and make their way into it by passing through the openings of the sebaceous glands. The guinea worm is transmitted in a similar manner, but in this case the intermediate host is a crustacean of the genus Cyclops. The embryos do not occur in the blood but escape from the female worm directly into water. They enter the bodies of the crustacea in which a metamorphosis occurs. The human being becomes infected through drinking water in which cyclops harbouring the parasites occur.

*Arthropoda.*—Parasitic arthropoda in many ways stand apart from other parasites. Many of them are purely ectoparasites which live outside the host. They vary in the degree of association. The ticks of the genus Ornithodoros, bedbugs of the genus Cimex, reduviid bugs of the genus Triatoma and allied forms, together with blood-sucking flies such as mosquitoes, sand-flies (see SAND-FLY FEVER) and tse-tse flies, visit their hosts only when blood is required. They can hardly be regarded as parasites. Fleas are more intimately associated with their hosts in that they spend at least some part of their life in the clothing and do not thrive if separated from them. Lice are still more dependent and quickly perish if removed from association with their host. The chigger flea *Sarcopsylla penetrans* at one stage of its existence is a true parasite. Males and females live apart from the host and only suck blood when this is needed. When they reach maturity fertilisation takes place and the female fixes itself to the skin by its proboscis and gradually works its way through the epidermis till it is lodged in a pocket. It becomes globular in form and produces a large number of eggs, which escape in the pus which discharges through the opening. The eggs reach the ground, where hatching of larvae, pupation and arrival at the adult stage take place.

The itch mite *Sarcoptes scabiei* has a similar life-history but the whole development takes place on the surface of the skin till the fertilised female produces the characteristic lesion by burrowing through the epidermis before laying eggs. Various diptera, the larvae of which develop usually in decomposing material, like the common blue bottle fly, may lay their eggs in wounds, and give rise to a condition known as myiasis. The larvae hatch and feed on the breaking down tissues till pupation occurs, when they are discharged. These larvae are only secondarily parasitic. They feed on decomposing material whether in a wound or on the ground. But having commenced to feed on decomposing tissues *in situ* they aggravate the lesion and produce an extension of the necrotic area. Other flies, particularly the Oestridae, actually deposit their eggs on healthy skin, the larvae burrowing beneath the epidermis. When fully grown, the larvae pupate and fall to the ground. Certain Muscidae are truly parasitic in the larval stage. Thus *Cordylobia anthropophaga* lays its eggs on the skin. The larvae which hatch bore their way through the epidermis and attain maturity and pupate in the subcutaneous tissues. The fly *Dermatobia cyaniventris* is of interest in that the fly does not deposit its eggs directly on the skin but on the body of mosquitoes, from which the larvae migrate while the mosquito is sucking blood. The larvae of *Auchmeromyia luteola*, the Congo floor maggot, lives in cracks and crevices but sucks the blood of human beings at night, returning to its hiding place after a feed, like the common bedbug. The adult fly is not a blood feeder.

*Reproduction of Parasites.*—The above brief summary indicates the type of parasitism which occurs in connection with human disease. Transmission is either direct or indirect. When it is direct the stage of the parasite which is outside the body is either completely passive, as in encysted forms of Protozoa and the eggs of many helminths, or active, as in the case of larvae of hookworms and many bacteria. During the active stage reproduction may or may not occur. The larvae of hookworms do not reproduce, though those of *Strongyloides stercoralis* are capable of doing so outside the human intestine. Many parasitic bacteria like those of enteric and cholera (see CHOLERA) multiply in water or other situations. When transmission is indirect and two or more hosts are necessary for the completion of the life cycle the course of development may or may not be associated with reproduction. The embryos of filariidae merely undergo a metamorphosis but do not reproduce.

The number of parasites which are capable of infecting man from one mosquito, for instance, is at most the same as the number of embryos originally taken up by the mosquito when it fed on infected

blood. In other cases definite multiplication occurs. A pair of male and female gametocytes of a malarial parasite are able to give rise to hundreds of sporozoites in the salivary glands of an anopheline mosquito. The sporozoites, however, are unable to reproduce, so that when they have all been discharged the mosquito is no longer capable of transmitting the disease. A single miracidium of a Trematode, like *Schistosoma haematobium* or *Fasciolopsis buski*, can in the mollusc give rise to a large but limited number of cercariae, whereas a single egg of the tape worms *Taenia solium* and *Taenia saginata* will give rise to a single scolex in the pig and ox respectively.

In the case of *Trypanosoma gambiense* and *T. rhodesiense*, which give rise to sleeping sickness, the flagellates which invade the salivary glands of tse-tse flies are constantly reproducing, so that infectivity is maintained probably for the duration of life of the fly. Similarly in the case of *Triatoma megista*, the vector of *Trypanosoma cruzi* of South America, the infection of the hind gut, once acquired, is retained for the rest of life.

Thus, in the case of certain parasites, even when multiplication in the intermediate host occurs, the forms taken up by the vector can give rise only to a limited number of infective stages, while in others the number is limited only by the length of life of the host. Similarly, in the case of man himself, the behaviour of the parasite varies. The various bacteria which attack him reproduce indefinitely in his body, the only check being the development of protective substances which destroy many of the organisms. The same condition obtains in malaria, trypanosomiasis, spirochaetosis and many other diseases. Metazoan parasites, however, do not as a rule reproduce in the body of man. If only a single larva of a hookworm penetrates the skin only a single adult could be found in the intestine. If only one ascaris egg were eaten only one adult would be developed from it. A single cercaria of *Schistosoma haematobium* or other trematode will give rise to only a single adult, while a single scolex of a tape worm eaten in fish, pork or beef will give rise to but a single tape worm in the intestine.

In all these infections, if a large number of parasites is present a corresponding number of infective forms must have entered the body. It follows therefore that if active reproduction does not occur in the human body the persistence of infection depends on the length of life of the individual parasites. In certain instances this may extend to many years, as in the case of *Schistosoma haematobium*, but in all such cases, when the infection is not a heavy one and reinfection can be avoided, the ill effects may be slight and a cure occur owing to the death of the parasite. The only Metazoan parasite which can be said to reproduce in the human body is the tapeworm *Taenia echinococcus*. It differs from other tape worms of man in that man is not infected with the actual tape worm stage. This occurs in the intestine of the dog. The egg, which escapes in the faeces of the dog, is eaten by man. A large hydatid cyst is developed and in it a number of scolices is produced. Each scolex will give rise to a single tape worm in the dog.

**Reservoir Hosts.**—Another aspect of the parasitology of man which is of great importance is that of reservoir hosts. Certain parasites which attack human beings are capable of living in other hosts without disturbing them to any marked extent. The existence of such hosts in close association with man is a serious danger. The bacillus of plague lives in rats, human beings being constantly infected by fleas which have fed on these animals. Pigs harbour the ciliate *Balantidium coli*, and the majority of cases of balantidial dysentery in man are in those whose work it is to tend these animals. The wild game of Africa act as reservoirs of various trypanosomes and it is highly probable that tse-tse flies may infect themselves from these animals with *Trypanosoma rhodesiense* and later on hand the infection to human beings. Wild rats very commonly harbour the spirochaete of Weil's disease and it is extremely probable that they are responsible at least in part for maintaining a strain of organism which not infrequently infects human beings. Similarly these animals are reservoirs of the *Spirillum* of rat bite fever.

**Development of Antibodies.**—It might be expected that those parasites such as the bacteria, malarial parasites, trypanosomes and spirochaetes which reproduce rapidly in the human body would very soon be present in overwhelming numbers. In certain instances this actually happens when the strain of parasite is said to be a highly virulent one. Fortunately in the majority of instances such an unlimited development is checked by the development in the host of antibodies which are harmful to the parasite. The exact nature of these substances and the method of their production are questions for the immunologists (see IMMUNITY) to settle, but the degree of response on the part of the human host as regards the rate of production of antibodies varies considerably. In the case of relapsing fever antibodies are

rapidly produced in sufficient quantity quickly to destroy all the organisms. Similarly in various bacterial diseases production of antibodies in many cases leads to rapid elimination of the parasites. In syphilis, tuberculosis and many other chronic infections antibody production may be sufficient to check reproduction to some extent but insufficient to kill all the organisms, which continue to multiply slowly and produce toxins which give rise to the characteristic symptoms of the diseases. As a general rule, antibody production is much more marked in bacterial diseases than in those caused by Protozoa and Metazoa. Methods of vaccination (see VACCINE THERAPY) have been devised for increasing the antibody production, while the introduction of antibodies, previously produced by vaccination of animals, into the human host after infection has occurred is a recognised method of treatment in such diseases as diphtheria, tetanus and possibly yellow fever.

**Idiosyncrasy and Immunity.**—An important feature of invasion of the body by parasites is the varying effect they have on different individuals. In one individual the parasites introduced multiply so rapidly that the host is quickly destroyed, while in another reproduction may take place so slowly that any slight derangement which occurs is overlooked. Sometimes, this is due to a variation in virulence of the parasite itself or, in other words, in its capacity for multiplication. In most instances, however, it undoubtedly depends on what is termed the susceptibility of the individual. Certain individuals are able to produce antibodies more rapidly than others, while some have them present before exposure to infection takes place. If they are present in a sufficient amount the parasites introduced are immediately destroyed. Such individuals are said to be naturally immune and they resemble in many respects those who are immune as a result of an actual infection from which recovery has occurred, or a vaccination which has led to the artificial production of antibodies.

**Carriers.**—Others, again, are only relatively immune, and though the parasites introduced establish themselves they give rise to few, if any, symptoms. Such infections very frequently pass unnoticed. They may rapidly come to an end or may persist for long periods (see EPIDEMIOLOGY; CEREBRO-SPINAL FEVER). In the latter case the individual is known as a carrier, for, though in him the parasite apparently does little harm, it may find its way into another individual who possesses no natural immunity and give rise to very serious or fatal infections. Such carriers are actually reservoirs of infections like the reservoir animals mentioned above. Carriers of this type occur with *Entamoeba histolytica*, the cause of amoebic dysentery (see DYSENTERY). Individuals have retained their infections for many years without having suffered from any of the symptoms which the amoeba may produce in others. On the other hand, when an infection takes place the parasite may reproduce rapidly and give rise to definite symptoms, which finally subside. The individual may no longer realise his infection, though parasites can still be demonstrated. He has passed into the carrier condition and is known as a convalescent carrier, to distinguish him from the contact carrier who has acquired the infection without having suffered in any recognisable way. Carriers of both kinds are of even greater danger to the community than actual sufferers from diseases, for they are often unrecognised and may be a constant source of infection to others. Outbreaks of enteric fever are repeatedly traced to carriers who quite unknowingly have been disseminating the parasites which cause the disease.

**Importance in Therapeutics.**—A complete understanding of the life histories of parasites, the response of the host to infections and finally the effect of drugs is of the utmost importance in the prevention and treatment of disease. If the life history of a parasite is completely known, an attack upon it may be made at any stage of its life history, but the measures can be more drastic in the case of stages which are outside the human body.

**Malaria.**—Since human beings never become infected with malaria parasites except from the bites of anopheline mosquitoes, malaria will be exterminated if all anopheline mosquitoes can be destroyed in a district, if individuals can avoid their bites, if the mosquitoes can be prevented from feeding on already infected persons, or if parasites can be eliminated from the bodies of infected individuals. Any one of these measures properly carried out will lead to the same result.

**Guinea Worm.**—Infection with guinea worm is acquired by swallowing the crustacean Cyclops into which the larvae which escape from the human host into water penetrate. The simple procedure of straining water through a fine mesh prevents the crustaceans being ingested. Eggs of the hookworm, if deposited in soil, hatch out larvae which penetrate the skin. The institu-

tion of latrines to avoid contamination of soil stops the larvae developing in dangerous ground, while the wearing of suitable coverings for the feet prevents the larvae from reaching the skin.

*Bilharziasis.*—The cercariae of species of *Schistosoma*, after they emerge from molluscs, survive in water for not more than 48 hours, so that water which has been kept for this length of time is not infective. The avoidance of known contaminated waters for washing and bathing purposes prevents infection.

*Other Bacterial Diseases.*—Many bacterial diseases, such as enteric fever and cholera (see CHOLERA), are contracted chiefly from water in which the organisms can survive and multiply. The drinking of boiled water alone and the avoidance of contamination of food or feeding utensils prevents infection. The extermination of rats, which act as reservoirs for the bacillus of plague, hinders the spread of the disease. The illustrations indicate the importance of the study of parasitology from the point of view of preventive medicine. When the complete life history of any parasite is known, an attack can be made upon it with confidence.

*Treatment of Hosts.*—As regards the response of the host to infection, a study of the causes which bring about the natural elimination of parasites from the human body has a direct bearing on treatment directed towards the production of active or passive artificial immunity and the period of isolation necessary for complete disinfection.

Finally, the effect of drugs on parasites is most important, both from the point of view of the individual infected and from that of the spread of infection to others. If by treatment parasites can be got rid of in any individual, he is cured of his infection and ceases to be a source of danger to others.

*Specific Remedies.*—An enormous amount of work has been done and is still in progress in connection with the search after specific remedies for each infection and the mechanism of action of such as have been discovered. This is one of the most difficult problems which confront the investigator, for both the effect of a drug on the parasite and the influence it may have on the host have to be taken into account (see PHARMACY; PHARMACOLOGY). Recent investigations show that in many cases the view that a drug introduced into the body of a host directly attacks the parasite is erroneous. In many, if not all, cases the actual substance introduced is not that which affects the parasite. The fluids and tissues of the host react upon it chemically so that some derivative is the actual toxic agent, or the drug itself stimulates the cells of the body to produce secondary substances which are injurious to the parasites. Such specific agents are quinine for malaria, emetin for amoebic dysentery, organic arsenic compounds for syphilis and relapsing fever, antimony salts for kala-azar and schistosomiasis. Though the administration of these drugs to infected persons rids them of their parasites, the exact mechanism of the action has not been elucidated. Many of these specific remedies have no action whatever on the parasites outside the body of the host.

*Parasites as Therapeutic Agents.*—The antagonism between one parasite and another is now being applied to the treatment of disease. In certain stages of infection with the spirochaete of syphilis the artificial infection of the host with the spirochaete of relapsing fever or the parasite of malaria, both of which can be easily eradicated by treatment, so alters the environment of the original parasites that they cease to multiply and are apparently destroyed. The view that the one parasite directly attacks the other is hardly tenable. More probably the superimposed infection changes the host in such a way that he ceases to be suitable for the continued development of the spirochaetes originally present.

*Undiscovered Parasites.*—In many cases in which there is evidence that disease is due to parasitic invasion of the body, the causative organism is known and much information regarding its life history has been obtained. In some instances, however, the parasite has still to be discovered. It has not yet been definitely decided whether the bacillus of Pfeiffer or a filterable virus is responsible for influenza (see INFLUENZA). The parasite which gives rise to the common cold is still unknown, while there is no precise information regarding any organism which can be held to be the cause of smallpox. Encephalitis lethargica, or sleepy sickness, and several other diseases are in a similar position, but the advances which are constantly being made in the methods of investigation will undoubtedly solve the many problems which surround these diseases, the etiology of which is still obscure.

**PARATYPHOID FEVER:** see INFECTIOUS FEVERS.

**PARAVANE.**—The paravane was developed during the World War, in connection with the anti-submarine and anti-

mine campaign, as a means of attacking submerged submarines for which purpose it was fitted with an explosive charge and called an explosive paravane. Subsequently it was further developed as an anti-mine device, and when used for this purpose was called a protector paravane.

#### THE EXPLOSIVE PARAVANE

A considerable amount of auxiliary apparatus was required in connection with the explosive paravane, the whole installation being called the high speed submarine sweep. It enables a vessel to attack a submerged hostile submarine whose position is but approximately known. It consists essentially of two torpedo-shaped bodies called paravanes, which are towed one on each quarter of the attacking vessel. Each paravane contains an explosive charge, and runs at a definite and pre-arranged depth below the surface of the sea, whilst the speed of towing makes it move outwards a certain distance from the fore and aft line of the ship.

The paravanes are towed from steam winches by specially prepared armoured electric cables, led over fairleads in the stern of the attacking vessel. The towing wire takes up a curve of definite shape which is practically independent of the speed.

*Methods of Detonating.*—The charge may be detonated in one of three ways: (1) by impact; (2) by strain; (3) by hand.

When the towing wire fouls a submerged submarine it will slip over her smooth surface until eventually the submarine is struck by the paravane. The striking gear which is fitted to the nose of the paravane is moved inwards by the impact and thus a firing switch is actuated and detonates the charge.

An alternative device for detonating the charge is fitted in case the first does not operate. If, as might easily happen, the nose of the paravane does not strike the submarine, the wire will in consequence be held up or will be nipped over some part of the submarine's hull, when an excessive load comes upon the wire. Any load above a predetermined one trips a dynamometer switch which will again make the electrical contact requisite to detonate the charge.

The third method of detonating the charge is by a hand switch on the attacking vessel, and meets the case when it is desired to get rid of the paravane purposely, either to meet some sudden emergency necessitating full speed, or to blow up the paravane on some marked spot such as a patch of oil escaping from a supposed damaged submarine.

*Spread of Sweep.*—The maximum spread of the sweep is about 30 yd., i.e., 60 yd. from paravane to paravane, and about 120 yd. of towing wire are then required for each paravane. Due to the design of the paravanes, this spread can be obtained independently of the depth at which the paravanes are being towed.

The "Q" type paravane herein described consists essentially of a torpedo-shaped body carrying a plane which gives the necessary thrust to get the maximum spread, and a rudder actuated by a hydrostatic valve to give the requisite depth of running independently of the amount of towing wire veered. In addition to the hydrostatic valve, the paravane carries within it a charge of T.N.T., depth-recording gear, firing switch, detonators, etc.

The advantages of this type of paravane are: (1) It can be towed at high speeds. (2) It leaves unaffected the manoeuvring powers of attacking vessels. (3) Being light it is easily handled. (4) It is not dangerous under shell fire when stowed on board.

*Construction.*—The paravane is divided into four parts, viz.: (1) head; (2) bonnet; (3) body; (4) tail.

*The Head.*—The head carries externally the tow anchorage, plane and striking device, and internally the gear for transmitting the effect of the impact to the striker-switch.

*The Bonnet.*—The bonnet is a steel dished plate carrying the striker-switch and depth-recording gear. The depth-recording gear registers on the attacking vessel the depth at which the paravane is running. The bonnet, carrying with it the striker-switch, lies wholly within the head, but the depth-recording gear, fastened to the after side of the bonnet, lies within the body of the paravane. Both the bonnet and body are made watertight.

*The Body.*—The body is made of steel plate  $\frac{1}{8}$  in. in thickness, and is acetylene-welded to ensure watertightness. The body carries within it the charge of T.N.T., the primer tin and the detonating gear. The most complex part is the detonating gear, which derives

its complexity from the arrangements necessary to prevent the charge from detonating whilst the paravane is on board or in close proximity to the ship. As now arranged, the detonators are withdrawn from the primer tin, and the two safety shutters, being simultaneously dropped, form an effective fire screen between the two. This safety device is in operation whilst the paravane is on board or moving at a slow speed through the water. At a speed greater than about 10 knots, a water flap, which projects from the under side of the paravane, is forced aft by the water pressure upon it. This movement is transmitted by linkwork to a detonator carriage, which moves aft, forcing the safety shutters to one side and placing the detonators in position in the primer.

**The Tail.**—The tail consists of a bronze casting and carries the two rudders, the hydrostatic valve which actuates the rudders, and the horizontal and vertical fins. When the paravane is required to run at a certain depth, a compression corresponding to this depth is put upon the hydrostatic valve spring. This load due to this compression forces the rudders "down." The water pressure acting on the hydrostatic valve, however, tends to force the rudders "up." When the two balance, the rudders return to the amidships position and so keep the paravane on a course which undulates about the set depth. This apparatus was fitted in the Allied navies as well as to the British Navy. The official record of the results is as follows, as regards the British Navy alone:—

Submarines known sunk 5; probably sunk 1; probably severely damaged 4; and probably slightly damaged 11.

### THE PROTECTOR PARAVANE

The protector paravane installation is designed to protect ships of all classes from moored mines. On either side of the vessel, by means of a length of special wire, is towed the paravane, a torpedo-shaped buoyant body. These paravanes stand out at a considerable lateral distance from the fore and aft line of the ship, and remain at a definite depth below the surface of the water. The planes and fins with which the paravanes are fitted have therefore a considerable thrust at high speeds, and this load is transmitted to the ship through each towing wire. But the towing wires constitute, indeed, one of the protective elements of the installation.

Due to the position taken up by the paravanes, the wires lie in a wedge-shaped position on either side of the ship, and sweep through a broad path. If they foul the mooring wire of a mine, the mine is deflected away from the path of the vessel. Not only so, but the mooring wire will slip along the paravane wire until it reaches the paravane. There it is caught in a cutter fitted on the head of the paravane which severs the mine from its mooring. The buoyant mine springs to the surface, where it can be readily seen and destroyed. The location of the position at which each towing wire leaves the vessel is clearly very important. In practice the towing wire is attached to the vessel at a specially designed permanent fitting situated on or near the line of keel and as far forward as practicable.

**Different Types.**—When the towing wire fouls a mine mooring wire, a minimum outward thrust must be imparted to the mine and sinker in order to deflect them from the path of the vessel. It is computed that this thrust is over half a ton, and must be imparted independently of the type of paravane fitted if the protection is to be of any value. Difficulties arise on this account when dealing with vessels of widely different speeds. If a paravane be designed to give this thrust whilst moving at a moderate speed through the water, its total thrust when moving at a high speed would be very great, and an excessive load would be thrown upon the towing wire. Two different types of paravanes are therefore constructed, according to the maximum speed of the vessel to which they are to be fitted, viz., Type "B," for battleships and large vessels, whose speed is under 22 knots; and Type "C," for cruisers and vessels, whose speed is over 22, but does not exceed 28 knots (see fig. 1).

In each type of paravane the towing rope can withstand the load produced when the vessel travels at her maximum speed, whilst the paravane itself provides the minimum outward thrust at the lower speeds necessary to deflect the mine. Since the outward thrust produced by a paravane increases approximately as the square of the speed, the range of speed over which the paravane remains effective is reduced as the maximum speed for which the paravane is designed is increased. Broadly speaking, however, a suitable paravane will protect a vessel at all speeds

from about one-third her maximum upwards. The effective speed of a paravane also depends upon the beam of the vessel to which it is attached—the throw-out necessary for a battleship is, for example, much greater than that for a mine-sweeper or other similar small vessel. Hence a "B" type paravane is effective for the latter class of vessel at a much lower speed than it would be in the case of a battleship.

**Buoyancy.**—At an early stage in the experimental design of the paravane, it was found that buoyant and non-buoyant paravanes were equally effective. The non-buoyant paravane has, however, been discarded for two reasons. Firstly, there would be a possibility of the paravane being damaged. When the ship slows down or stops in shallow water, the paravane would sink to the bottom. A rocky bottom would probably have a disastrous effect

FIG. 1.—Diagrams illustrating the general arrangement of two types of paravane.

upon a paravane when the ship went ahead again. Secondly, the horizontal angle of tow would vary with the speed. The excess of the weight of the paravane over its buoyancy being constant and acting vertically downwards, would, when compounded with the varying outward thrust of the plane, give a resultant force whose direction varied constantly. Hence the angle from the vertical at which the paravane was towed could not remain at all speeds. The greater the excess of weight over buoyancy of the paravane, the greater would be the variation of this angle. This would cause the paravane to run deeper and deeper as the speed decreased. Although this is not a drawback from a protection standpoint, it is a considerable disadvantage from a navigation standpoint, seeing that the virtual draught of the ship increases as her speed is reduced. With a buoyant paravane, should the vessel be compelled to stop suddenly, the paravane, being buoyant, will float on the surface and support the towing wire. It will always sink to its set depth when the vessel is under way, as long as the speed is only a little above two knots.

**Length of Towing Wire and Spread.**—The protection afforded by the paravanes depends, amongst other things, upon the distance from the fore and aft line of the ship at which the paravanes are towed. This distance or spread in turn depends upon three things:—(1) the length of the towing wire; (2) the size of the paravane; (3) the size of the towing wire.

**Depths of Tow Points and Paravanes.**—The paravanes must be attached to the ship as far forward and as low down as practicable. If the point of attachment were above the level of the keel, a mine could pass under a towing wire and hit the ship. The point of attachment usually selected is the point of intersection of the fore perpendicular with the line of keel. This en-

tails the design on all warships of a permanent fitting or stem extension.

Further, the paravanes should not tow at any considerable depth below the keel line of the ship. If they did so, and the ship travelled from deep into shallow water, the paravanes might strike the bottom and be destroyed. As moored mines are usually laid in shallow water, the paravanes are arranged to run at little greater depth than the maximum draught of the vessel using them, and at approximately a constant depth, no matter how the vessel to which they are attached varies in speed. An essential feature of the paravane design is, therefore, a rudder actuated by a hydrostatic valve. This valve can be set to run at a definite depth before the paravane is thrown overboard. When a paravane is fitted with this gear, the depth at which it runs does not vary more than 4 ft. on either side of the set depth.

The paravane is usually set to run at a depth which is about 5 ft. in excess of the deepest draught of the vessel. The paravane towing wire and the tow point are thus practically in a horizontal plane in which also lies the keel of the vessel. Any mine within the sweep of the paravanes, which lies between the line of keel and the surface of the sea, must therefore be deflected by the towing wire. If a mine be moored so deeply that it passes under the towing wire, it cannot, under ordinary circumstances, strike the ship in calm water. The paravane attachment does not claim to be an absolute protection to a pitching vessel.

**Oscillator.**—The depth-keeping mechanism in the paravane is composed of two distinct portions, the hydrostatic valve and the mercury oscillator. The hydrostatic valve depends, for its action, on a change of depth above or below the normal depth. It therefore causes the paravane to follow a sinusoidal path through the water. At high speeds this motion becomes excessive and a device is required which will return the paravane to its correct position as soon as it is inclined to move from its set depth. This function is performed by the oscillator. It is the same in "B" and "C" paravanes, and is composed of a triple valve, comprising two mercury valves and one hydrostatic valve, and a compression spring.

**The Cutter.**—The cutter requires no setting, and can take the two parts of a mine mooring in rapid succession. The cutter supplied is very effective, and will sever a 1½ in. wire with a pull of about seven cwt. Further experiments show that this cutter will sever a ¾ to ½ in. chain at a speed of 20 knots. Since it is impossible to moor any existing design of mine with such a large diameter chain, this cutter will be sufficiently effective for every size of mine mooring likely to be found in practice.

Its efficiency may be illustrated in another way. It cuts a mine mooring with no greater pull than that afforded by the mere weight of the mine sinker. It is therefore impossible for the mine and sinker to be towed by the cutter. As an example of the performance of these cutters, the results of tests made on three cutters selected at random are appended:—

|       | Cutting Pull (lb.) |     |     |     |         |
|-------|--------------------|-----|-----|-----|---------|
|       | A                  | B   | C   | D   | Average |
| No. 1 | 854                | 780 | 797 | 636 | 767     |
| No. 2 | 945                | 833 | 833 | 847 | 864     |
| No. 3 | 670                | 749 | 721 | 693 | 708     |

These tests were made on an imitation German mine mooring rope. The loads were applied statically, starting at 300 lb. and rising by small increments.

**Conditions under Helm.**—It is desirable to consider not only the conditions when the vessel is steaming on a straight course, but also those when she is moving under helm. As already described, an effective paravane will deflect any mine from the path of a vessel which is on a straight course, but it is conceivable that, whilst a vessel is turning, a mine may be missed by the bow paravane and hit the ship near the stern. From this it is apparent that such a ship when under full helm sweeps out a pathway about 300 ft. wide.

In arranging that, as far as possible, the paravanes should sweep the sea clear of all mines which approach the outer side of a vessel swinging round under moderate and, if possible, manoeuvring helm, there are two cases to be considered. For relatively small ships, such as protected cruisers and all smaller vessels, one pair of paravanes gives practically complete immunity from moored mines as long as the ship is not in a heavy sea. With larger ships, however, the distance swept out by the vessel

herself when turning under full helm may be so great that one pair of protector paravanes does not give adequate protection.

**Horse-power Absorbed.**—The following table gives the shaft horse-power absorbed at different speeds for the two types of paravanes when using the normal (56 yd.) length of wire. Of course, if the length of the wire be decreased, the resistance to motion and hence the shaft horse-power absorbed is reduced. On the other hand, if the length of wire be increased, the shaft horse-power absorbed is also increased.

|               | Type "B"<br>Paravane |     |     |       | Type "C"<br>Paravane |       |       |       |
|---------------|----------------------|-----|-----|-------|----------------------|-------|-------|-------|
|               | 16                   | 18  | 20  | 22    | 18                   | 22    | 26    | 28    |
| Speed (knots) | 16                   | 18  | 20  | 22    | 18                   | 22    | 26    | 28    |
| H.P. absorbed | 450                  | 620 | 870 | 1,170 | 640                  | 1,100 | 1,780 | 2,230 |

The above figures are deduced from actual tests on the measured mile, and represent the horse-power absorbed by the paravane system. The shaft horse-power absorbed on any particular ship may, however, differ slightly from the above figures on either side, seeing that the propellers will then be working under different conditions and will consequently have different efficiencies, but the above figures should be correct to within 5% for any particular vessel. The official record of the results obtained shows that British warship tonnage that, but for protector paravanes, would have been either sunk or seriously damaged, totalled 583,713 tons.

**The Otter.**—When the Admiralty decided to equip British merchant vessels with paravane protection, a simpler form of paravane called an "otter" was introduced. It is in all respects the same type of device as the protector paravane, excepting that the mercury oscillator is removed. The removal of the mercury oscillator renders the otter unstable above 14 knots. Since the average speed of a merchant vessel is 10–13 knots, the otter gave good service in practice.

#### CHRONOLOGY.

Sept. 1914. Provisional scheme and design of explosive paravane submitted to British Admiralty by Lieut. C. D. Burney.

May 1915. High speed submarine sweep tested in H.M.S. "Mastiff" at Harwich and approved for supply to H.M. Navy.

March 1915. Provisional design of protector paravane submitted by Lieut. C. D. Burney.

Nov. 1915. First successful trial in H.M.S. "Melampus" of protector paravane.

Feb. 1916. Protector paravane successfully demonstrated to Grand Fleet, and approved for supply to H.M. Navy.

April 1917. First merchant vessel fitted with "otters." (When the Armistice was concluded, 3,000 merchant vessels had been fitted with otters.) (C. D. B.)

**PARDO BAZÁN, EMILIA** (1851–1921), Spanish author (see 20.800), died in Madrid May 12 1921.

**PARENT, SIMON NAPOLEON** (1855–1920), Canadian politician (see 20.801), died in Sept. 1920.

**PARIS** (see 20.804).—In modern times Paris has grown rapidly and had, in 1921, a population of 2,906,472. In 1910 it counted nearly 90,000 houses while the built-over surface had increased to 2,775 hectares, the area of gardens, yards and unoccupied ground having somewhat diminished. The public transport services carried 994,000,000 passengers in 1912 as against 552,000,000 in 1901, while 29,000,000 passengers used the ceinture railways and the Auteuil line, and 100,000,000 passed through the Paris railway termini.

During this period Paris was not yet the industrial centre of France that it became after the War. In 1911 it produced one-sixth of the total production (excluding agricultural) of France. On Jan. 1 1911 Paris proper had only 14,075 factories, though there were many more in adjacent districts. Nevertheless, by 1914, Paris was among the leading producers of the metal, chemical, pottery, glass, hides and leather, food and timber industries. All great French commercial, banking and industrial businesses have their headquarters there, or at least maintain an office, and many foreign enterprises are represented. Paris represents an enormous concentration of wealth from every source, mainly localised in the west end and in contrast to the great areas of poverty in the east end and on the outskirts of the districts on the left bank of the Seine, and many places in the suburbs which

have grown up chaotically and in defiance of hygiene and of town-planning. By 1913 motors had superseded horse transport for practically every purpose in the public transport system.

In 1912 the Boulevard Jules-Ferry was opened, and in 1913 the Boulevard Raspail, which had been begun under Napoleon III. In 1913 also the reconstruction of the bridge of Notre-Dame was begun, to be finished during the War. The square of Parc-Royal was opened in 1913; the square Jules-Ferry in 1922 and Saint-Séverin in 1923. The Palais de Justice was completed by the southeast wing 1911, the new Hôpital de la Pitié was opened, in 1917 a model lycée was built (the Lycée Jules Ferry in the rue de Douai), and the Cour des Comptes was opened.

#### THE CITY DURING THE WORLD WAR

Immediately on outbreak of war the theatres were closed Aug. 3 (1914), cafés and restaurants were closed after 8 P.M. Aug. 4; women at once began to take the places of men in occupations such as public transport. Refugees poured in from the invaded districts; on the other hand many Parisians left the city, and the Govt. withdrew temporarily to Bordeaux. On Sept. 3 the Bourse was closed. The same day was placarded the proclamation of the new Governor of Paris, Gen. Gallieni, promising to defend the city to the last. After the victory of the Marne the danger passed. Theatres partially reopened at the end of Nov., the Bourse on Dec. 7; on Dec. 10 the Govt. returned. Paris gradually became an immense arsenal; the working-class population, including foreigners and women, rose to 61,000 in Jan. 1915, to 144,000 in April 1916, then to 300,000 in Nov. 1918. Factories like those of Renault and Citroën were characteristic of this war-time stimulus to industry. Taubes had flown over the city on Aug. 30 1914; in March 1915 Zeppelins appeared; they bombarded Paris Jan. 29 1916. Then came the first restriction—that on coal, begun in the winter of 1916-7. Queues for milk, chocolate, etc., became features of Paris streets. Ration cards were introduced with War bread, frozen meat, saccharine for sugar. In Jan. 1917 restaurant menus were cut down and in Feb. confectioners, pastry-cooks and tea-rooms were partially closed. In May meatless days were introduced. Prices began to rise. To keep them down, municipal butchers' shops were opened in May 1918.

Bombardments became more intense in 1918; during this year Gothas dropped bombs 14 times. On March 23 the long-distance gun, nicknamed "Big Bertha," began to play its part and on March 29, Good Friday, killed 88 persons in the church of S. Gervais and wounded 68. Long-distance guns bombarded Paris and its suburbs on 44 days, killing 256 persons and wounding 625. In consequence of the frequent air raids, street lighting was reduced at night to a minimum. Works of art were protected with sand-bags.

On Nov. 11, at 11 o'clock, salvos and carillons announced the Armistice. The crowd held joyful demonstrations along the great boulevards and on the Place de la Concorde, decorated with War trophies. A pendant to this occasion was July 14 1919, when the triumphal procession of victorious troops passed under the Arc de Triomphe de l'Étoile. But the economic consequences of the War continued. Bread cards were only abolished on June 1 1919, coal cards on Jan. 13 1921. The municipality had to fight the high cost of living; in Feb. 1919 it established a kitchen at Billancourt to supply cheap meals and on March 6 it opened the first Vilgrain stalls where foodstuffs were sold below market prices. During the period 1919-21 no less than 164 stalls were opened and for the same purpose restaurants for the masses of the people were opened in various parts of the city.

#### PARIS AFTER THE WAR

Paris was greatly changed by the War. Many of the immigrants remained; war industries remained and were adapted to peace purposes. Thus a large new industrial population had to be housed. The old fortified enceinte was abolished in 1919, its area was set apart for cheap dwellings or barracks or, with certain limitations, for private building. The 250 metre-wide zone round it was reserved for parks and playgrounds, the obsolete

forts of the first line of defence and the site of the second line of forts left open to provide reservoirs of air. On Aug. 1 1919 a competition was opened for a plan for the laying out and extension of Paris. In 1923 the Conseil Général de la Seine acquired the park of the ancient Château des Sceaux for recreation and building purposes; the Pelouse d'Avron for building sites; and a vast site near the Courneuve and Bourget where a new town will be built. Many of the new suburban houses are on the garden city model. A university "Cité" for students has been built near the Montsouris Park.

Overcrowding is worst in the suburbs and outskirts of Paris. The population of the central *arrondissements* has declined owing to offices replacing dwellings; the total population of Paris increased by only 18,362 between 1911 and 1921 (2,888,110 and 2,906,472, respectively), while that of *l'arrondissement* of Saint-Denis rose by 139,869 and of Sceaux by 99,418. The total population of the department, including Paris, was 4,567,690 in 1926, an increase of 224,344 since 1921. The growing suburbs are now connected with Paris. The population of the Seine included 300,000 foreigners in 1921, that of Paris, 170,000 in 1925. The intense shortage of houses has accentuated the need for a housing policy. The public office for cheap houses for Paris was created in Jan. 1914; for the Dept. of the Seine, July 1915. By March 31 1922, the city, the department, their offices and the Assistance Publique had built 2,731 dwellings, 935 more were nearly completed, 5,110 under construction and 4,052 projected. Public surface transport in Paris was amalgamated in 1921. In 1924 1,070,000,000 passengers were carried by these vehicles; 575,000,000 on the Métropolitain and the Nord-Sud railways. The vastly increased traffic (which caused 60,000 accidents in Paris in 1920) necessitated many regulations. The gyratory system has been adopted at suitable points; that of one-way traffic for certain parallel streets. Mechanical signals allow momentary halts to enable foot-passengers to cross the streets, slow vehicular traffic is prohibited in certain streets at the rush hours. Fresh undertakings of the municipality are the completion of the Boulevard Haussmann, the reconstruction of the old bridge of la Tournelle and the transference of the Morgue to the outskirts of Paris; new undertakings of the Government of France are the grave of the Unknown Soldier and the exhibition of decorative arts of 1925.

*The Port.*—The port of Paris, which, independently of the Seine, includes the three canals of the Ourcq, Saint-Denis and Saint-Martin, which unite in the dock of la Villette, is being enlarged; three important ports are under construction at Bonneuil, Gennevilliers and Pantin; a port is to be established at Bobigny and connected with the future canal between Pantin and Saint-Denis; docks are also projected at several points in the old fortified enceinte, the deepening of the Seine is also proposed. A canal to unite the Marne from d'Annet to the Seine in the neighbourhood of Saint-Denis is intended to protect Paris from inundation.

A bureau for employment and labour statistics was created in 1915 for the department of the Seine, labour bureaux already in existence in the mayoral divisions of Paris were linked up with it in 1919. In 1924 the bureau found work for 308,000. The same department founded in 1918 the public bureau of social hygiene, whose principal object is to fight against tuberculosis; it has established dispensaries and controls sanatoriums; it has instituted fresh air schools and preventorium; it also sends children to the country. The average figure of mortality from pulmonary tuberculosis in Paris, which from 1894 to 1898 was 3.62 per 1,000 inhabitants was reduced to 2.31 in 1920. Similar progress has been made in the provision of municipal baths, the bathing establishment of the Butte-aux-Cailles and the stadium at the Rue des Tournelles are new features for Paris.

Electric power has been centralised for Paris since 1914 by the Compagnie Parisienne de distribution d'électricité, which has rented the electric cable from the municipality and supplies the city from its stations at Saint-Ouen and Issy-les-Moulineaux. The number of customers, which on Jan. 1 1914 was 132,000, rose on Jan. 1 1924 to 379,000. With all this the municipal budget has not risen since the War, if account be taken of the depreciation of the franc; expenditure was 494,000,000 in 1911 and 1,550,000,000 in 1925. Meanwhile new fields are constantly opening for its activities with the general use of reinforced concrete, with the new architectural forms which it introduces, and the spread of mechanical devices. The new social city seems about to succeed the old princely city.

**PARIS, CONFERENCE OF.**—The conference for framing the treaties which ended the War was held in Paris in 1919-20.

## I. PRELIMINARIES

*The Pre-Armistice Agreement.*—Germany faced complete defeat and unconditional surrender when, one after the other, her allies Bulgaria, Turkey and Austria-Hungary broke under the strain of war in Sept. and Oct. 1918, and sought terms with the enemy. Germany saw her best chance in overtures to the President of the United States, whose speeches during months past had underlined the principles necessary to the restoration and preservation of world peace (see **FOURTEEN POINTS**). Accordingly on Oct. 4 the German Govt. despatched a note to Wilson through the Swiss Govt. requesting an armistice.

In reply, President Wilson laid down the stipulations that before negotiations for peace could be opened: (1) Germany must accept without qualification the principles of the Fourteen Points, leaving for discussion only the practical details of their application; (2) the German armies must be withdrawn from all territories of the Allies under the direction of the Allied military authorities so that there could be no question of the military supremacy of the armies of the Allies and of the United States in the field; (3) Germany must cease all illegal and inhuman practices and abandon unlimited submarine warfare, before an armistice could be granted; and (4) the German nation must free itself of the arbitrary Govt. which had conducted the War. The German authorities were reluctant to accept such terms for the cessation of hostilities. Gen. Ludendorff resigned rather than accede to those conditions, but the civil Govt., although it protested against the charges of illegal and inhuman practices, despatched a note on Oct. 20 accepting the stipulations of President Wilson as preliminary to an armistice. With Germany committed to a programme, Wilson then presented the matter to the Allies. The President had already sent Col. Edward M. House to Paris as American representative on the Supreme War Council. He met with the Allied leaders, Lloyd George, Clemenceau and Orlando, to discuss, first, whether an armistice should be granted, and second, whether Germany's request that the Fourteen Points be used as the basis of peace should be accepted.

President Wilson has been much criticised on the ground that he was responsible for too early a peace, and that had it not been for him terms would have been dictated to Berlin. This is far from the truth. The Allied Council agreed to grant the Armistice on the recommendation of the military leaders; the Americans were in fact less eager than the French and the British for the cessation of hostilities. To be certain of Allied sentiment regarding the Armistice, House asked Marshal Foch directly whether or not from a purely military point of view he would prefer to have hostilities cease on the terms proposed. Foch replied that, since the terms demanded of Germany were practically the same as those that would be demanded at Berlin, he was opposed to the useless sacrifice of another life. "*On ne fait la guerre que pour ses résultats.*"

The Allied leaders were more doubtful as to whether President Wilson's Fourteen Points should be taken as the basis of the peace, as Germany asked. Clemenceau, Lloyd George, Hymans and Orlando each raised objections. They finally agreed, however, upon the strong insistence of Col. House, to accept the Fourteen Points with two reservations regarding the freedom of the seas and restoration of invaded territory. Acknowledging these reservations, Wilson on Nov. 5 communicated the reply of the Allies to the German Government. This note is of vital importance. "It constitutes the formal and written offer of the Allied and Associated States to conclude with Germany (a) an armistice convention and (b) a treaty of peace. This offer, it is conceived, was accepted by Germany by the act of sending representatives through military channels, to meet Marshal Foch for the purpose of arranging an armistice. By the acceptance of the offer a solemn Agreement was reached which served, both morally and legally, as the basis of the armistice convention and the treaty of peace."<sup>1</sup>

<sup>1</sup> Temperley, *A History of the Peace Conference of Paris*, I., 382.

The note of Nov. 5, in which Wilson stated that Marshal Foch would communicate the conditions of an armistice, contained the text of the memorandum of observations by the Allied Governments on the correspondence between President Wilson and Germany. In this memorandum those Governments "declare their willingness to make peace with the Govt. of Germany on the terms of peace laid down in the President's Address of Jan. 8 1918 (the Fourteen Points), and the principles of settlement enunciated in his subsequent Addresses," subject to two qualifications. These reserved complete liberty, as regards the "freedom of the seas," and interpreted "restoration of invaded territory" as meaning that "compensation will be made by Germany for all damage done to the civilian population of the Allies and their property by the aggression of Germany by land, by sea and from the air."

Both the Allied and Associated Powers and the Germans accepted this Pre-Armistice Agreement as the basis of the peace. The protests of the German delegation against the Versailles Treaty in May 1919 were based upon their allegation that the treaty was not in accord with the principles of the agreement. The Allied and Associated Powers, although they denied the validity of the allegation, explicitly acknowledged the validity of the basis: "The Allied and Associated Powers are in complete accord with the German delegation in their insistence that the basis for the negotiation of the treaty of peace is to be found in the correspondence which immediately preceded the signing of the Armistice of Nov. 11 1918."<sup>2</sup>

*Organisation of Peace Conference.*—The question whether the President of the United States should come in person to Europe and participate in the negotiations was one of the first importance. The statesmen of France and Great Britain had reason to fear for the satisfaction of their particular interests if the creator of the idealistic programme were there to apply his principles to practical details. Their misgivings, perhaps, were somewhat allayed by the assurance that the French Premier, Clemenceau, would preside over the Conference. They decided to welcome President Wilson and to take their chances with his point of view.

Representatives of the chief Allied and Associated Powers—France, Great Britain, Italy, Japan and the United States—held consultations in Dec., and the first plenary session of the Peace Conference did not take place until Jan. 18 1919. President Wilson did not reach Europe until Dec. 13 1918. The British Prime Minister, Lloyd George, was detained at home by the political uncertainties of a general election until after New Year. So important to any negotiations was the participation of these two heads of governments that nothing definite could be attempted until their arrival. In the meantime, the smaller Powers which had been overrun by the armies of Germany had time to reorganise their governments and to send plenipotentiaries to the Conference who could speak with responsibility.

The Peace Conference was called by the five principal Powers to assemble at Paris. Geneva had been suggested as a neutral meeting-place for victors and vanquished, but the opinion prevailed that the enemy should be excluded from the conference until summoned to hear the terms which must be accepted. Brussels also was suggested in appreciation of Belgium's heroic rôle in the War, but the honour was finally given to France. The War against the Central Powers had been directed from France; there sat the Supreme War Council of the Allies, and upon this the structure of the Peace Conference could most readily be erected.

Even while in the throes of war, and by no means certain of victory, the Allies had begun to study the problems of peace. Departments of the French Govt. had prepared plans. The British Foreign Office had established an organisation in 1917 to examine the issues for settlement. In the United States Col. Edward M. House at the request of President Wilson had organised "The Inquiry," a body of experts under the chairmanship of Dr. Sidney E. Mezes of the College of the City of New

<sup>2</sup> Reply of the Allied and Associated Powers to the Observations of the German Delegation on the Conditions of Peace.

York for gathering statistics and correlating necessary data. Other nations also had begun to prepare their cases against the Central Powers for presentation before the high tribunal of the forthcoming Peace Conference. In no case, however, had responsible heads of states made as yet the adjustments necessary between the facts of the past—economic, political and diplomatic—and the requirements for the international order of the future. Despite the fact that early in the War the leading Powers had realised the necessity of technical information and specialised knowledge, the Peace Conference was faced with the task of working crude materials into an intricate design for peace.

## II. ORGANISATION OF THE CONFERENCE

*The Council of Ten.*—Upon the arrival of Lloyd George in Paris, a meeting of the Supreme War Council was held, Jan. 12 at the Quai d'Orsay. France was represented by Clemenceau and Pichon, Great Britain by Lloyd George and Balfour, Italy by Orlando and Sonnino, the United States by Wilson and Lansing. Though ostensibly an informal conversation among plenipotentiaries of the four leading Powers, the meeting was the occasion of the significant decision to add only the representatives of Japan to the Supreme Council and to exclude all others from the major decisions of the Peace Conference. Thus the Council of Ten sprang from the Supreme War Council. There also came to Paris the representatives of Belgium, Serbia, Rumania, Greece and the other States—32 in all—which had fought against the Central Powers or had broken off diplomatic relations with them. Obviously it was impossible for all to have equal part in determining the conditions of peace. To each, seats and a vote were allotted in the plenary sessions of the conference. Representatives of those states which had remained neutral during the War, and yet had interests to safeguard or to advance at the Peace Conference, were permitted to attend only those sessions which were arranged for discussion of their claims, whenever they were specially summoned by the five chief Powers. It had been the intention of the latter, at first to put on the same footing the new states which were rising from the ruins of the Central Powers. Before the first plenary session, Poland and Czechoslovakia were conceded representation in the conference; but Yugoslavia—including Serbia, Montenegro and the south Slav provinces of Austria-Hungary—was not officially recognised until the end of May, chiefly because of the opposition of Italy.

*The Delegates.*—Outstanding among the delegates from the smaller Powers were Hymans, Foreign Minister of Belgium; Paderewski, Premier of Poland, and his Foreign Minister Dmowski; and Bratianu, Premier of Rumania. For Serbia and the south Slavs came Pasitch, Vesnitch and Trumbitch. Veniselos came to speak for Greece. For Czechoslovakia came its Premier, Kramarsz, and the brilliant young Foreign Minister, Benés. The new Kingdom of the Hedjaz was represented by the Emir Feisal, in striking Arab robes. These were but a few of the many dignitaries from every part of the world who soon crowded the hotels of Paris. It was easily recognised that all who came to represent their countries could not be included even in the plenary assembly of the conference. The number of plenipotentiaries for each state was, to be sure, merely a matter of sentiment, for no Power could have more than one vote.

But there was considerable dispute before the five principal Powers finally assigned places in the conference to each state in accordance with its military strength and its share in the War. Five seats were given to each of the five chief Powers; three apiece were assigned to Belgium, Serbia and Brazil; two each to Canada, Australia, South Africa, India, China, Czechoslovakia, Poland, Greece, the Hedjaz, Portugal, Rumania and Siam; one each to New Zealand, Bolivia, Cuba, Ecuador, Guatemala, Haiti, Honduras, Liberia, Nicaragua, Panama, Peru and Uruguay. Many delegates were thus left out, but the panel system was adopted so that all Powers could use their plenipotentiaries in rotation if they desired. Representatives of the British Dominions, for example, more than once shared in important decisions of the Supreme Council by reason of their membership in

the panel of the British Empire. Other important work was found later for excess members of several delegations on commissions and subcommittees.

When the plenary assembly of the conference met for the first time on Jan. 18 it proved to be only a body of approval merely passing upon actions that had already been determined in the Supreme Council. Clemenceau was elected president of the conference. A *secrétariat-général* previously selected by the Supreme Council was appointed. A drafting committee was approved, on which had been placed only representatives of the five chief Powers. The smaller Powers endeavoured to protest against such rigid control by the Five. But at the second plenary session on Jan. 25 Clemenceau bluntly dismissed their objections with allusion to the 12,000,000 soldiers behind the authority of the five Powers. Having the greatest interests at stake, they were determined to keep political decisions well in their grasp. The smaller Powers could turn their energies into labour upon the technical commissions.

*Administrative Work.*—With this matter of authority arbitrarily arranged, the Peace Conference settled to the work of constructing a peace. Peace-making, however, was not to be its sole task. It was obliged also to assume executive duties of tremendous consequence. It must direct the Allied Armistice Commission at Spa. It must set up and control the Supreme Economic Council at Paris. It had to maintain its own authority over Poland, Germany, Hungary, Czechoslovakia and Rumania. The Supreme Council of the Conference administered the Armistice by instructions to Marshal Foch, who in turn forwarded them to the International Commission at Spa. The Allied members of the commission consequently had no authority to make any decision beyond their instructions. They did have full power to explain and to stress important points in the Allied interpretation of the Armistice and, by personal intercourse, to prevail upon the German representatives to accept the decisions of the Supreme Council at Paris. The matters that chiefly concerned the Armistice Commission were: the withdrawal of German forces from the territory of the Allies and their demobilisation, the repatriation of prisoners interned in Germany, surrender by Germany of the required amounts of arms, airplanes, mercantile and agricultural machinery, locomotives and railroad equipment, and the delivery of other commodities stipulated in the Armistice. There were accompanying financial and commercial questions to perplex the Allied representatives and to jeopardise the renewal of the Armistice until the conference had prepared terms for peace.

*Supreme Economic Council.*—At the instance of President Wilson on Feb. 8 the Supreme Council resolved to create a Supreme Economic Council of five members each from interested Powers. It was to advise the conference upon the temporary economic measures necessary pending the completion of negotiations for peace. During the War, several Inter-Allied organisations had grown up to deal with the problems of purchase, transportation and distribution of foodstuffs, nitrates, copper, petroleum and war materials of all sorts. In addition, there had been organised various programme committees, a Supreme Blockade Council, a Supreme Council of Supply and Relief, and the like (*see* CONTROL, INTER-ALLIED).

At its first meeting on Feb. 17 the Supreme Economic Council decided to co-ordinate the work of all these War boards and to direct them as sections of its own organisation. As a result, matters of food and relief were placed under Herbert Hoover of the United States as director-general; matters of finance, under Norman Davis of the United States; the problems of communications were ultimately assigned to Brig.-Gen. H. O. Maine of Great Britain; raw materials, to Loucheur of France; problems of blockade, to Vance McCormick of the United States; and shipping to Cooke of Great Britain.

The Supreme Economic Council endeavoured to supply devastated areas with materials necessary for reconstruction and to revive the economic activity of those countries which were victims of the War. It was especially concerned with the problem of relieving the famine-stricken areas of Eastern Europe—a

situation recognised as dangerous to political stability and likely to encourage the spread of Bolshevism. It arranged the Brussels Agreement by which Germany was provided with foodstuffs, to carry out that provision in the Armistice which pledged the Allies to revictual Germany in return for cash payments. It delegated to a sub-committee the special task of economic administration in the territories of Germany occupied by Allied armies. It carried on direct negotiations with the German Finance Commission, studied the economic effects of the Allied blockades of Bolshevik Russia and Hungary, and urged the Supreme Council of the conference to relax those blockades for the benefit of the peoples of other states near by. It relaxed the blockade against Germany and reorganised the transportation systems of Austria, Hungary and Poland.

In short, the Supreme Economic Council under the honorary chairmanship of Lord Robert Cecil, although established only as a temporary commission to administer economic affairs until the advent of peace, became one of the most important international bodies directing the reorganisation of Europe. After the Treaty of Versailles had been signed, it continued to act as agent for the Allies, to secure foodstuffs in America and to supply Austria with coal. The importance of some common economic body until the League of Nations should get under way was beyond question. The Supreme Council of the conference therefore decided to request that the Supreme Economic Council should continue at work, with some changes in its organisation. Political opposition interfered with the proper development of the Council into an International Economic Council, but before its last meeting at Rome, Nov. 21 1919, it had drawn up significant proposals for co-operative purchase and distribution of foodstuffs, coal and raw materials by the nations of Europe.

*Hostilities on Eastern Fronts.*—The authority of the Peace Conference was menaced seriously not only by the hostility of the enemy, Germany, but by the resistance of the ally, Rumania, and the new governments of Poland and Czechoslovakia. Early in Nov. 1918 hostilities had broken out between the Poles and the Ruthenians in East Galicia, where Polish proprietors constituted a landed minority, and Ruthenian peasants, closely related to the Ukrainians in Russia, were in a majority. During Feb. 1919 an Allied Mission intervened, but the Ukrainian commander refused to accept the proposed truce. In March the Supreme Council of the Peace Conference arranged another truce with the Ukrainian commander, and on April 2 set up an Inter-Allied Commission at Paris to arrange the terms of an armistice concerning Eastern Galicia. The Polish delegation rejected this armistice on the ground that Poland's safety required military occupation of East Galicia. In the end the Supreme Council sanctioned the Polish occupation. The ultimate status of Eastern Galicia was left for later decision.

To safeguard Poland on its western border, the Peace Conference imposed an obligation upon Germany that had not been stipulated in the Armistice. In Posen, where Germans constituted in large part the class of landed proprietors and Poles were the peasants, local conflicts developed during Dec. 1918 between garrisons and Polish volunteer forces. The Peace Conference finally in Jan. 1919 despatched an Inter-Allied Commission to stop these hostilities and served notice of that intention upon Germany through Marshal Foch. Germany protested, but practically accepted the provisional line of demarcation as laid down by the Allied Commission until the boundaries of Germany and Poland should be determined by treaty (see *VERSAILLES, TREATY OF*). Germany also objected strongly to the transport of Gen. Haller's Polish army from France to Poland via Danzig, on the ground that its presence would prejudice the ultimate disposition of Danzig. The conference forced Germany to admit the technical right of the Allies to use Danzig as such a port of entry to Poland, but allowed Germany to route Haller's army via railroad without touching Danzig. The Peace Conference was further annoyed by Germany's delay in withdrawing the forces under Gen. von der Goltz from the Baltic States where they were holding a line by agreement with Soviet Russia (see *BREST-LITOVSK, TREATY OF*).

Still more vexatious to the Peace Conference, perhaps, was the situation that developed in Hungary after the establishment of a Bolshevik régime under Béla Kun. The armistice of Nov. 3 1918 had been concluded between the Italian Supreme Command and the command of what was theoretically still the army of Austria-Hungary. But Poles, Czechs, Yugoslavs had already declared themselves independent. The German Austrians and the Magyars also had dissolved their old union. It was a real question, therefore, whether the terms of an armistice in behalf of a state no longer in existence bound the new Govt. of Hungary. On Nov. 13, accordingly, Franchet d'Esperey signed a military convention with the delegates of the Hungarian Government. On March 19 1919 the French officer heading the military mission in Budapest presented to the Karolyi Govt. a demand that all Hungarian forces be withdrawn behind a line corresponding to that fixed by the Rumanian Treaty of Aug. 13 1916. Karolyi seized the opportunity to distort the demand and to resign power to the Hungarian proletariat and Béla Kun.

On April 1 the Supreme Council of the conference dispatched Gen. Smuts to Budapest to find out whether Béla Kun's Govt. would recognise the validity of the military convention and would accept temporary military occupation by Allied troops of the zone between Hungary and Rumania as marked by the lines laid down by the Allied Powers. Béla Kun's Govt. agreed to withdraw its troops if Rumania would withdraw to a line further east than that temporarily fixed by the conference in Feb., and if Allied troops occupied the entire area in dispute. Smuts rejected this suggestion. Thereupon Hungarian troops moved out to meet Czechoslovakian and Rumanian forces that had already advanced into the disputed region. The Czechoslovaks had occupied important coal areas. Béla Kun decided to attack them first, breaking their liaison with the Rumanians and perhaps opening a way for Bolshevik forces to come over the Carpathian Mts. from Russia.

The Hungarian Army penetrated into Czechoslovakia before the Peace Conference intervened. On June 13 the conference summoned Rumania and Czechoslovakia to withdraw their troops behind the new frontiers which they were to be allotted. Béla Kun then ordered the Hungarian forces to withdraw from Czechoslovakia and, in turn, called upon the Peace Conference to make the Rumanians withdraw from Hungarian territory. But the Rumanian Govt. declined to do so until the Hungarian Army had been reduced to the six infantry and two cavalry divisions stipulated in the Armistice. On July 17 the Allied commander in southeastern Europe, Gen. Franchet d'Esperey, under orders from Paris, demanded that Béla Kun's Govt. retire in favour of one chosen by the Hungarian people. A wireless message from the Peace Conference on July 25 declared its willingness to negotiate with such a government.

In the meantime, Béla Kun thought to win favour with the Hungarian people by defying d'Esperey and by launching an attack upon the Rumanian forces. The Rumanian Army, however, resisted so successfully that by Aug. 8 it had rolled back the Hungarian Army and was in occupation not only of most of Hungarian territory east of the Danube but of Budapest itself. The Peace Conference meanwhile had sent a mission of Allied generals to carry out the agreements of the Armistice. Rumania resisted the direction of the Supreme Council, and issued an ultimatum demanding a third of available farm animals and machinery, half of the railroad equipment, large quantities of munitions and river shipping. The Peace Conference protested repeatedly against Rumanian actions and, securing the resignation of the Hungarian Govt. which had been established upon Rumanian approval, finally succeeded in getting Rumania to withdraw its troops and to accept those goods which it had exacted from Hungary as part of its share of reparations.

Still other matters to distract the Supreme Council of the Peace Conference from its major task of peace-making were the sharp controversies between Czechoslovakia and Poland over Teschen and between Austria and Yugoslavia over Klagenfurt. The situation in Russia caused much discussion during the first

days. Decision was reached on Jan. 22 that all the Russian factions should be summoned into consultation on the island of Prinkipo, in order to determine who was to be responsible for Russian interests at the Peace Conference. But nothing came of the effort: Neither the old Tsarist order, the revolutionary Govt. of Kerensky, nor the Bolshevik régime of Lenin were represented at the Peace Conference. Nor were the new Baltic States—Finland, Estonia, Latvia, Lithuania—which were breaking away from the old Russian Empire.

In view of such difficulties, it would seem remarkable that the statesmen at Paris ever reached common ground for any settlement. But, harassed as it was by executive duties, the Peace Conference went steadily forward with its peace programme.

*Official Language.*—Two preliminary questions of procedure for a time disturbed the plenipotentiaries at Paris. What was to be the official language of the conference? Should its proceedings be made public? It was decided that French and English texts, of equal authority, should be presented in the treaty with Germany which included the Covenant. Italian texts, along with English and French, were presented in the Austrian, Hungarian and Bulgarian treaties; and in all these the French version was declared to prevail in case of divergence. The languages of the enemy states were denied admission to the texts of the treaties. With regard to publicity for the actions of the conference, the decision was reached to withhold details of discussions as much as possible until definite understandings had been secured. The sessions of the Supreme Council, the commissions and committees must be in secret; for obviously, diverse interests could only be reconciled by compromise. It was better that the public concerned should not know the details of the bargaining, if there was to be future satisfaction with the settlement.

In addition to its burden of executive duties, the Supreme Council had to listen for hours to the special pleas of Rumanians, Greeks, Czechoslovaks, Arabs, Belgians, Syrians and Druses, Serbs and Croats, and Slovenes, Danes, Albanians, Armenians, Zionists. The Council soon realised that under such circumstances it could not make rapid progress toward an effective settlement unless other agents were put at work on the multitude of complex issues. The conference, therefore, was organised into commissions and sub-committees, over 50 in all, to study assigned problems, to hear expert testimony, to weigh opposing claims of interested parties, to debate rival policies, and to report to the Supreme Council, with which remained the final decision. Reference has been made above to the councils and missions employed for executive duties.

*Special Commissions.*—Among the special agents established to assist in making a peace were commissions on: (1) Responsibility for War and Guarantees, with Lansing of the United States as president, and sub-committees on criminal acts, responsibility for war, responsibility for violation of laws and customs of war; (2) Reparation for Damage, with Klotz of France presiding and sub-committees on estimation of damages, financial capacity of the enemy, and means of payment and reparation; (3) International Labour Legislation, with Gompers of the United States presiding (*see* INTERNATIONAL LABOUR); (4) International Control of Ports, Waterways and Railways, with Crespi of Italy as president and sub-committees on transit and control of routes of communication; (5) Financial Questions, with Montagu of Great Britain presiding, and sub-committees on financial problems preliminary to peace, on monetary questions, enemy debts and so on; (6) Economic Questions, with Clémentel of France as president and sub-committees on permanent commercial relations, tariffs and customs, navigation, industrial property and others; (7) Aeronautics, with Colonel Dhé of France as president; (8) Inter-Allied Naval and Military Affairs, under the presidency of Marshal Foch, which with other associated committees constructed the military and naval and air terms for presentation to the enemy; and (9) The Central Commission on Territorial Questions, over which Tardieu of France presided, to co-ordinate the work of the committees and commissions that had been assigned from time to time to the difficult tasks of examining the complex problems of Czecho-

slovakia, Poland, Rumania, Yugoslavia, Greece, Albania, Belgium, Denmark, the Saar Valley and Alsace-Lorraine.

As it proved, these territorial commissions could do little more than recommend that the Peace Conference accept and maintain the situation of each area practically as the War had left it. So deep were prejudices, hatreds and interests, that rebuilding of the states of Europe as the result of purely disinterested and scientific investigation was impossible. In all of these agencies of the Peace Conference the five Allied and Associated Powers kept for themselves either the entire membership or at least a majority over the representatives of the smaller Powers which were included.

### III. COVENANT OF THE LEAGUE

First and most important of all was the commission on the League of Nations, chosen on Jan. 25 at the second plenary session of the conference upon the recommendation of the Supreme Council. The membership of this commission was drawn from the political leaders of 14 nations. Among them were Lord Robert Cecil and Gen. Smuts of the British Empire, Bourgeois of France, Orlando of Italy, Hymans of Belgium, Veniselos of Greece, Vesnich of Serbia, Wilson and House of the United States. The commission met on Feb. 3, and after daily sessions in the Hotel Crillon (held at hours that did not conflict with the meetings of the Council of Ten) presented to the plenary session of the conference on Feb. 14 the first draft of the Covenant. The usual procedure at the conference, of translating into French when English was used and into English when French was spoken, lengthened the sittings twofold and, while necessary, consumed much time. On the other hand, at the meetings of the commission to form the Covenant for the League of Nations, interpreters sitting by those who did not speak both languages, kept them informed in an undertone of the progress of the discussion. It was agreed by the commission to use as a basis for discussion the American plan for the Covenant prepared by Wilson and House, which had, by consent, been put into legal phraseology by Sir Cecil Hurst and David Hunter Miller, legal advisers respectively of the British and American delegations. There were several difficult problems to solve, one or two of them causing some rancour. Of these the question of political equality and that of having a league with an army at its command to enforce its decisions, advocated by the Japanese and French respectively, caused the most acrimonious debates. These finally were settled to the satisfaction of a large majority of the commission, although there was a small and resentful minority against the decisions reached.

The debate in the plenary session—the one important discussion in that body throughout the period of the conference—resulted in approval of the principle of the Covenant and brought forward various suggestions for amendment. President Wilson left on the following day for necessary executive duties in the United States. The Covenant as first drafted met stubborn resistance from the leaders of the Republican party in the United States. They argued that Article X, which committed each member of the league to respect and to preserve as against external aggression the territorial integrity and existing political independence of all other members, encroached upon the exclusive right to declare war which had been given to Congress by the Constitution of the United States. They declared that the league would destroy the Monroe Doctrine. They insisted that a state should be allowed, without sinister implication, to withdraw from the league if it saw fit. These, and many others, were objections raised in America.

The Covenant was revised by the commission and finally approved by the fifth plenary session of the conference on April 28, without change of a single word. It is to be doubted whether there were many sitting at that historic table who realised that with the acceptance of the Covenant a new phase of civilisation had begun and that the League of Nations was its keystone. The Covenant specifically provided for safeguarding the Monroe Doctrine against actions by the league; it contained a clause to permit any state to withdraw upon giving notice of its intention

two years in advance. A Japanese proposal for a clause in the Covenant declaring the equality of members of the league without respect to race or colour, was vetoed through the insistence of Premier Hughes of Australia. A French proposal to provide the league with a general military staff and with power to supervise disarmament also failed to win the approval of the commission. An American proposal to forbid discrimination in fiscal and economic regulations between one nation and another—a plan to eliminate *Zollvereins* and imperial preference—was likewise discarded. Finally, the chief objection to the Covenant raised in America was passed over. With the full support of President Wilson, Article X., so obnoxious to some Republicans in the United States, was retained in the Covenant.

#### IV. PROGRESS OF PEACE MAKING

*Council of Four.*—Four days after President Wilson left for the United States, Clemenceau was shot by a fanatic. Although not dangerously wounded, he was confined to his home. Col. House, who had been delegated to take Wilson's place, came to meet him there and, with the return of Lloyd George from England, the same group was reformed which had worked with celerity and success during the Armistice proceedings. Thus the Council of Four took form. The Japanese plenipotentiary, Marquis Saionji, might well have claimed the right to attend also, but he held to the Japanese policy of standing off when Japanese interests were not concerned, especially when the matters under discussion pertained purely to a European problem.

Upon Wilson's return to Paris, March 14, he replaced House in these informal conferences. The four heads of states abandoned the Council of Ten. It was reduced to the five foreign ministers. Whenever they desired, the Four assumed the authority of the Ten as the Supreme Council of the Peace Conference, and drew apart to confer in private. The ministers of foreign affairs continued to sit as a Council of Five, although they were concerned chiefly with minor executive duties and other matters of routine. But, while the Four were still engrossed in negotiation with the recalcitrant German delegation, the Five went ahead with discussion of the terms to be given to Austria. The power of the Peace Conference, however, had been drawn into the hands of four men, and moreover, in the last resort, the Italian, Orlando, found that final decision belonged really to the Three—Clemenceau, Lloyd George and Wilson.

No one listened to the arguments of the Four except their interpreter, Capt. Paul Mantoux, and later their secretary, Sir Maurice Hankey, who rendered invaluable service by keeping the minutes of their discussions and by drafting the resolutions upon which they agreed. On occasion, experts were summoned to give data and technical advice; inter-Allied commissions were formed directly by the Four and ordered to report to them; but speeches, special pleas, formal audiences and other time-consuming devices were thrust aside.

*National Claims.*—When Wilson returned to Paris, March 14, the problem of meeting the claims of France, Italy, Belgium and Japan immediately became acute. The French asked for continued occupation by the Allies of the Rhineland and the bridgeheads of Cologne, Coblenz and Mainz. Unauthorised demands were made for the permanent separation from the Reich of German territory on the left bank of the Rhine. France asked further for complete sovereignty over the Saar Valley, as compensation for its own mines which had been deliberately ruined by the German forces. The French representatives pressed vehemently for "integral reparation," assessment of actual damages done by the enemy and exaction of the total amount in reparation. France supported Poland's claim to complete sovereignty over Danzig and the approaches to that city.

Although at one time (April 7) President Wilson threatened to break off negotiations over these questions and return to the United States without finishing the task of peace-making, compromises that he could accept were found one after another. The scheme for a republic on the Rhine was repudiated, but agreement was reached that the left bank of the Rhine, and a

wide strip on the right bank, should be demilitarised and all fortifications razed, and that the Allies should maintain their joint military occupation for 15 years. It was to be continued if France, in the opinion of the Allies, was not then sufficiently secured against an unprovoked attack. The decision to prohibit union of Germany with Austria, described by Tardieu as one of Clemenceau's fundamentals, was taken in the second week of April, inserted in the first draft of the German Treaty in May and remained there in the definite text of June 28.

As for the French claim to the Saar Valley, the compromise was reached that France should have full ownership of the coal mines but that, on account of the 650,000 German inhabitants, government of the region should not be given to France but should be put under the control of the League for 15 years. At the end of that time, the inhabitants resident prior to this arrangement should vote for one of three settlements: the *status quo* under the League, union with France or return to Germany. In case they voted for return to Germany, France was to give back the mines and to receive compensation from Germany or the Reparations Commission which was to be created by the treaty with Germany.

*Reparations.*—The problem of reparation was not effectively solved by the Council of Four. Many English and American advisers, thinking of Germany's exhaustion, the danger of making the German people desperate and the mistaken policy of asking that a blank cheque be signed and handed over for the Allies to fill in, urged that Germany be cleared of charges for reparation by payment at once of whatever amount it could produce. The debate ramified into the uncertainties of Germany's capacity to pay and the largest sum for which Germany might be held liable. The French view prevailed. It was agreed that Germany should be held liable to pay to the last cent. The demands of the British and French that pensions should be included in the reparations bill were first opposed by Wilson, but he finally yielded (*see REPARATIONS*). The deadlock over Danzig was broken by Lloyd George who sought and found a way between Wilson's Thirteenth Point that Poland should have, free and secure access to the sea, and British fears that a *Germania irredenta* with 2,000,000 inhabitants might be created. Danzig was to be a free city under the protection of the League of Nations, but Poland was to have access through Polish territory to the Baltic Sea and virtual control over Danzig's interests abroad. Within a week after President Wilson had threatened to leave the conference, these differences had been ironed out so well that the representatives of Germany were invited to appear at Versailles on April 25.

*Crises over National Claims.*—But another crisis suddenly appeared. The Italians threatened to withdraw from the conference unless their claims to Austro-Hungarian territories were met before the Germans signed the treaty. These claims were grounded upon promises given by France and Great Britain in the secret Treaty of London (April 26 1915). Orlando went further, however, to claim the city and port of Fiume which had not been allotted to Italy by the secret treaty. In this case he argued for the principle of self-determination, although he had opposed the application of that principle to the German population in the Tyrol south of the Brenner Pass. Wilson gave way to Orlando's contention to the extent of agreeing that Italy's northern frontier should be extended to the Brenner. But he resisted the Italian pretensions on the eastern shore of the Adriatic; for they were advanced at the expense of Yugoslavia and Albania. Fiume had a large Slav population and a purely Slav hinterland. It was the natural seaport of the Slav and Magyar regions to the east. Wilson rejected the suggestion that Fiume should be given to Italy in exchange for the Italian renunciation of claims upon Dalmatia under the Treaty of London. On April 23 Wilson publicly declared his reasons for opposing Italian claims. Orlando and his foreign minister, Sonnino, left Paris for Rome, but returned after the conference determined to proceed with the German treaty regardless. They reached Paris on May 7, a day too late for the sixth plenary session, which approved the draft of the treaty, and only a few hours before it was handed

to the Germans at Versailles. The Italians were back in the Conference, but the question of the Adriatic was not settled.

Meanwhile the claims of Belgium, Yugoslavia and Japan further complicated the situation for the Council of Four. Hymans appeared on April 29 to demand that, as Belgium had been first to suffer in the War, she should be first to receive compensation for war costs. She had been promised as much in the Armistice. He asked that Belgium be given a prior lien upon \$500,000,000 of the first cash receipts from Germany and complete settlement of the Belgian account within 10 years. Eventually the American view prevailed, that Belgium's case was different from all others. Belgium was practically assured payment of her war costs by receiving a special issue of German bonds and priority on the half-billion cash receipts. Serbia immediately asked for \$400,000,000, but the Council of Four dismissed that claim summarily.

The Japanese issue, however, could not be settled so easily as the Belgian or the Serbian claims. The Japanese representatives took exception to the suggestion that the German area in Shantung should be handed back directly to the Chinese. Japan claimed Shantung on several grounds. By the treaties with China in 1915, following the "Twenty-One Demands," Japan had gained rights in Shantung, even if the Chinese authorities had continued to insist that those rights had been exacted by superior force. Further, a secret agreement in 1917 with the European Allies against Germany had assured Japan that those Allies would offer no objection to Japanese claims in Shantung, although the United States had never been a party to the agreement. Wilson resisted the Japanese claims to Shantung, but finally accepted a compromise on April 30.

The Italian crisis was threatening to disrupt the conference, and an understanding with Japan was more than ever necessary. It was to the effect that the Japanese were to keep Kiaochow and its adjacent district, with rights also to exploit the mines and railways in the peninsula; but that Chinese sovereignty would be restored over the peninsula of Shantung "as soon as possible." The American President expressed faith in the oral promise of the Japanese that Japan would eventually evacuate Shantung in favour of China and retain there only commercial concessions. The Chinese representatives at the Peace Conference did not have such faith. They refused to sign the treaty with Germany. But they gained a place in the League of Nations for China by signing the subsequent treaty with Austria.

#### V. TREATY OF VERSAILLES

With these crises over national claims passed, the draft of the treaty with Germany was handed to its chief representative, Count Brockdorff-Rantzau, on May 7 1919 at the Trianon. Without rising from his chair, the German hurled sharp words at the representatives of the Allies for their dilatory methods. In the past six months, he declared, the blockade had caused the deaths of hundreds of thousands in Germany. "Think of that," he said, "when you speak of guilt and punishment." He and his countrymen would accept the liabilities to which they were committed by the Armistice under the terms of President Wilson. They were prepared to play their part in restoring Belgium and the devastated areas of France. But they and their nation did not hope for a just peace. "We know," he said, "the power of the hatred that we encounter here."

*German Objections.*—The Germans were given 15 days, and then an extension of time, in which to present their objections to the terms of the treaty. They complained that the Allied plan for reparations was too severe and claimed the right of appeal from the assessment of the Reparations Commission to some neutral arbitrator. They demanded a plebiscite in Alsace-Lorraine. In place of the Allied arrangement for the Saar Valley, they offered fixed annual supplies of coal to France until the French mines should be restored. Instead of giving up Danzig, Memel and West Poland, they offered to make Danzig, Memel and Königsberg free ports under German sovereignty. They demanded that Germany's claim to its colonies should be referred to arbitration. They asked for reciprocity with regard to com-

merce and goods in transit. They offered to negotiate concerning the League of Nations, provided Germany were admitted immediately, the members of the League were pledged against waging economic war and the Allied Powers also should abolish compulsory military service within two years and disarm themselves. They desired that the armies of occupation should leave German territory within six months after the signing of the treaty. They summed up their criticisms with the charge that the treaty as a whole was inconsistent with the terms of the Pre-Armistice Agreement. Such an imputation was angrily rejected by the Allies, but suggestions were made in the Supreme Council of the conference that the terms of the treaty should be softened.

*Movement for Revision.*—Lloyd George, backed by members of the British Ministry and representatives of the British Dominions, led the movement for revision. He protested against maintaining for a considerable period of time a large army of occupation. He now favoured a fixed indemnity in place of the plan for reparations. Mr. Lloyd George advocated plebiscites for Upper Silesia, Allenstein and Marienwerder to meet German objections and also urged some changes in the Polish frontier. He wished to grant early admission of Germany into the League. But the dangers of further delay were apparent. It was hardly possible at so late a date to rewrite the treaty. The movement for revision came to an end on June 13 with the only consequence that some concessions were made to Germany on minor points.

The Allies maintained their position with regard to reparations and the armies of occupation. They conceded some changes in the Polish frontier, to make it more consistent with ethnographic divisions. They agreed to a plebiscite in Upper Silesia. They withdrew the provision for making the Kiel Canal an international waterway. They intimated that they would open negotiations at once looking toward reduction of their own armaments. They promised to admit Germany into the League, if Germany complied with the terms of the treaty. They invited from Germany an offer (hedged round with many conditions), within four months of the signing of the treaty, of a lump sum to settle the whole bill for reparations. This suggestion was not accepted by Germany.

There was suspense as Count Brockdorff-Rantzau presented the final terms of the Allies to the German Govt. at Weimar. The Allied Armies of Occupation prepared for a general advance into Germany if the Germans should refuse to sign the treaty. The Scheidemann Ministry resigned on June 20, and the new Premier, Bauer, offered on the next day to sign the treaty without its articles requiring the surrender of War criminals and declaring Germany solely responsible for causing the War. The Allies refused. In this tense situation, the crews of the German battle-fleet scuttled their ships in Scapa Flow. But on June 22 Bauer obtained the permission of the Weimar National Assembly to sign without conditions, and the new German Minister of Foreign Affairs, Müller, with his colleague, Dr. Bell, at last on June 28 signed the treaty in the Salle des Glaces at Versailles.

*Subsidiary Agreements.*—Dependent upon the Treaty of Versailles, although apparently the result of separate negotiations among the interested Powers, were several other treaties and international agreements: (1) two defensive treaties, each signed by France, first with Great Britain, and next, with the United States. The two latter Powers bound themselves to come to the aid of France in case of an unprovoked aggression by Germany any time within the next 10 years. Great Britain made her ratification dependent on that of the United States. The latter refused to ratify, and so both treaties became nugatory; (2) a protocol defining certain ambiguities in the Treaty of Versailles; (3) an agreement among the United States, Belgium, the British Empire, France and Germany to define the nature of the military occupation of the Rhineland; (4) a treaty between Poland and the Allies to assure protection of life and liberty to all inhabitants of Poland without distinction as to birth, nationality, language, race or religion. Similar protection was later secured by the Allied Powers for minorities in Czechoslovakia, Rumania and Yugoslavia, provisions which were not applied to Italy (*see MINORITIES; ST. GERMAIN, TREATY OF*).

*Ratification.*—The Treaty of Versailles was ratified on July 9 by Germany, and by Oct. Great Britain, France, Italy and Japan also had ratified. The exchange of ratifications was delayed for two reasons. First, it was hoped that the Senate of the United States would ratify at least with reservations. Second, Germany must make amends for the destruction of its fleet in violation of the Armistice. On Nov. 19 1919 the American Senate failed to ratify; but on Jan. 10 1920 Germany finally signed a protocol to give compensation for scuttling the fleet. Then the exchange of ratifications was made at Paris between the European Allies and Germany, and on Jan. 16 1920 the League of Nations was formally inaugurated.

## VI. OTHER TREATIES

After the Germans had signed the Treaty of Versailles on June 28 1919 the Peace Conference turned to the problems of Austria, Hungary, Bulgaria and Turkey, over which many of its commissions had been labouring for months. Chiefs of state began to resume their political tasks. Foreign ministers one by one left for home. Power to act in behalf of the respective states, however, was delegated to lesser dignitaries. The organisation of the conference remained intact to complete negotiations with the former allies of Germany. Austria was presented with terms drawn on lines similar to those granted to Germany. Her representatives signed at Saint Germain-en-Laye on Sept. 10 1919 (*see SAINT GERMAIN, TREATY OF*). And in Jan. 1920, Hungary, freed from its Communist régime and from Rumanian control, was accorded terms varying from the Austrian hardly more than in minor details. The Hungarians signed on June 4 1920 (*see TRIANON, TREATY OF THE*).

For Bulgaria, a delegation headed by Teodoroff, the Prime Minister, arrived in Paris on July 26 1919 but did not receive the draft of the treaty until Sept. 19. The Bulgarians delayed their reply more than a month to frame objections; but other than the promise for speedy admission into the League, they got no concessions from the Peace Conference. Further remonstrance from the Bulgarians led Clemenceau to give them 10 days to accept or to reject. By this time Teodoroff had lost power in Bulgaria, and Stambulisky, head of the Agrarian party, had taken control of the Bulgarian Government. On Nov. 27 1919, at Neuilly-sur-Seine, Stambulisky signed the treaty as the sole representative of Bulgaria (*see NEUILLY, TREATY OF*).

Following the establishment of the League of Nations on Jan. 16 1920 the Peace Conference came to an end. Several issues of first importance remained for disposal, among them the problem of the Adriatic and the settlement with Turkey. The plenipotentiaries left these matters, however, to the Conference of Ambassadors or to negotiation among the interested states. (*See AMBASSADORS, CONFERENCE OF*.) Italy continued to press her claims to Fiume and strategic points on the eastern shore of the Adriatic. Great Britain and France, though recognising their obligations under the secret Treaty of London, endeavoured to satisfy Italy with a compromise short of those obligations so as to gain the approval of the American Government. But Wilson persisted in opposition for the sake of the interests of Yugoslavia and Albania. The upshot of the controversy was that Italy secured the island of Sasseno outside the port of Valona, the port remaining in Albanian hands, and at a later date reached an agreement with Yugoslavia. Albania maintained her independence and on Dec. 17 1920 gained admission to the League of Nations.

*The Turkish Settlement.*—The Turkish question had been discussed at Paris in May and June 1919 and a Turkish deputation had visited the conference, but the drafting of the treaty was not taken seriously in hand until the London Conference of Feb. 1920. The delay was due in part to the hope that the United States would join in signing the treaty, but there were also great difficulties involved in the assignment of mandates over the national minorities in the Turkish Empire. Wilson's Twelfth Point had stipulated that these territories should receive "unmolested opportunity of autonomous development." An article in the Treaty of Versailles indicated that some of them at least

would be recognised as independent states, under such mandates as they chose to accept.

But there had been understandings among the Allies that ran counter to the principle of self-determination. In May 1916 France and Great Britain had made the Sykes-Picot agreement with regard to their respective spheres of influence in Turkey. The French sphere was to include Cilicia, southern Armenia and Syria. The British area was to include Haifa and Mesopotamia. Palestine was to be international territory. Greece claimed the whole of Turkish Thrace, the Aegean Is. and Smyrna, which Greek forces occupied in May 1919, with the approval of the Supreme Council of the Peace Conference. Italy claimed the Dodecanese, which it had held since the war with Turkey in 1912, and a sphere of influence on the adjacent mainland. Both France and the Hedjaz desired the Arab districts of Syria. The disposition of Constantinople also was uncertain.

On Feb. 16 1920 the London Conference of the Allies announced that Constantinople would remain the capital of Turkey; but a month later the Allies informed Turkey that this concession depended upon its good behaviour. Constantinople had been occupied by Allied troops under the command of Sir G. F. Milne before the end of 1918. On April 25, at the Conference of San Remo, mandates were given to France for Syria, Cilicia and the Lebanon; to Great Britain for Palestine and Mesopotamia, but the mandate over Armenia was declined both by the League of Nations and by the United States. Finally, on May 11 1920 the draft of a treaty similar in many respects to the Treaty of Versailles was handed to the Turkish representatives at Sévres. It was signed on Aug. 10 1920. (*See SÈVRES, TREATY OF*.) Thus the task of constructing terms of peace for the last of the enemies of the Allied and Associated Powers was brought to an end. Real peace, however, had not yet come to the world.

## VII. SUMMARY CRITIQUE OF THE CONFERENCE

The Peace Conference should have sat immediately after the conclusion of the Armistice, and should have made a preliminary peace to be followed later by a permanent peace. The belligerent nations had been so shattered by the War that the need for bringing about a resumption of normal conditions as soon as possible was imperative. The Armistice was signed Nov. 11 and, if the Peace Conference had convened by Nov. 20, a preliminary peace might have been signed by Christmas 1918. There was no necessity for the preliminary peace to cover more than three general conditions relating to the final settlement: the terms relating to military and naval affairs, the sum to be exacted for reparations and the delineation of German boundaries. The army and navy terms need not have been essentially different from those contained in the Armistice Agreement. The delineation of territorial concessions might have been given broadly as not exceeding certain lines, and the sum to be fixed for reparations likewise should have been flexible, both a maximum and minimum sum being stated. Much of the distress and many of the disasters which have overtaken Europe since 1918 might have been avoided by an early preliminary peace. There need have been nothing controversial in it and the Senate of the United States would have ratified it and, having ratified it, would probably have committed itself to the permanent treaty which might have been written at leisure.

*President Wilson's Position.*—It will always be a question of historical interest whether it was wise for President Wilson to go to Paris and venture himself into the controversies certain to arise. Some contend that without his influence the liberal part of the peace would not have been written, nor would the League of Nations have come into being. There are those who believe he should have remained the "God on the Mountain" at Washington and allowed others to negotiate for the American war aims, he having at all times a veto power and being beyond the reach of those who tried to use his influence in behalf of their own particular measures. That is in the realm of speculation, and no one may say with certitude which contention is right or which is wrong.

Clemenceau and Lloyd George at first did not look with favour upon his sitting in the conference. The reason they gave was that he was the head of a State and, if he participated in the conference, the kings of England, Italy and Belgium and the President of France might claim similar privileges. President Wilson was impressed by the argument when presented to him after he reached Paris, and indicated a willingness to be guided by it. One day, soon after the President's arrival, Clemenceau shifted his position and not only consented to his sitting in the conference, but even expressed a hope that he would do so. He undertook to guarantee that Lloyd George would also change his position and welcome the President as a colleague. It may be that after investigation they found that the sovereigns mentioned and President Poincaré would not press their claims to be present, or it may be that they concluded that if President Wilson entered the debating arena of the conference with them, he would descend from his high position and become as common clay. Or, Clemenceau, alarmed by the attitude of Lloyd George after the Armistice, may have felt he needed support from a strong and disinterested source to carry through what he had in mind for the safety and rehabilitation of France.

The delay in the meeting of the conference was less the fault of President Wilson than that of his principal colleagues. President Wilson might have come to Europe immediately after the Armistice was concluded, for his excuse that he had to remain in Washington for the purpose of delivering his message to Congress fails to carry conviction. He easily might have written the message and sent it to Congress, as was customary before he became President. But even if he had come immediately to Europe, it is to be doubted whether he could have hastened the date for the convening of the conference. Col. House urged an early convocation of the warring states and, had this come about, President Wilson would have responded and been present. As it was, when he did arrive on Dec. 14 1918, he found no one of his colleagues ready to begin. His visits to England and to Italy were made not to meet his personal desire to make them then but to fill in the time between his arrival and the earliest date he could obtain consent for the parleys to begin. Therefore, no more blame rightfully could be attached to him for this delay than for delaying, as was later charged, the conclusions of the conference by his insistence that the League of Nations' Covenant should be a part of the Versailles Treaty. The commission for the making of the Covenant worked mainly at night and at odd hours, and was the first committee to finish its duties and report to the conference, and it takes a large measure of imagination to bring so unjust a criticism against the President.

*Subjects for Discussion.*—When the conference first got down to work there was much confusion as to method and also as to the precedence to be given the subjects to be discussed. There should have been a well-defined programme laid out in advance so as to form a basis for discussion, as was done when the Covenant was formed. The lack of this caused the conference to waste time, and it resulted in the setting up of the ineffective Council of Ten which was, indeed, a council of 30 or 40 when the secretaries, experts and representatives of states interested were included in the meetings. The time of the council was largely taken up in listening to those who came to Paris to plead for certain boundaries affecting their countries. There were few on the council able to follow their arguments, and much time was wasted to no purpose. If the council had reached its own conclusions under advice of its experts, and then called in those interested to explain why such conclusions should not become part of the treaty, progress might have been made. After wasting many weeks in this futile endeavour to get at the facts and having failed, the Council of Four was substituted for the Council of Ten. Decisions then came rapidly. It was unfortunate that no one of the so-called Big Four possessed much organising ability; otherwise even greater progress might have been made.

*Reparations and Security.*—The question of reparations was the one great stumbling block of the conference, and the disagreements that arose in connection with it were the most

potent cause of the delay in the making of the treaty. There was common agreement that Germany should pay to the full extent of her capacity, but there was a wide difference of opinion as to what her capacity was. The heads of the British and French delegations demanded of Germany the entire cost of the War on land and sea. The American Commission deemed this impossible, and sought to have a sum named which Germany might reasonably be expected to pay. After weeks and months of fruitless discussion, President Wilson finally agreed to a compromise which amounted to Germany's signing a blank cheque to be filled in later. He consented to this because it was thought that the Reparations Commission which the treaty provided, would, of necessity, name a sum which could be met. No one then considered the possibility of the United States Senate refusing to ratify the treaty, and thereby bringing about the disastrous deadlock which has so seriously impeded Europe's economic recovery.

The question of French security ran through the discussions at Paris and finally was met by compromise. President Wilson and Lloyd George agreed on behalf of the United States and Great Britain respectively to come to the assistance of France in the event of an unwarranted invasion by Germany. The terms of the treaty were somewhat indefinite, but they were the best that Clemenceau, after long negotiation, was able to secure. Wilson and Lloyd George were adamant in refusing all proposals regarding the left bank of the Rhine as a permanent line. Clemenceau has been criticised for believing that the United States Senate would accept such a treaty, as indeed have all the Allied leaders for believing that the Senate would accept membership in the League of Nations.

As a matter of fact, if the Versailles Treaty had been accepted, the Franco-American Security Treaty also would have, in all probability, gone through; and the Versailles Treaty would have been ratified by the Senate provided President Wilson had been willing to accept the Lodge reservations. The Versailles Treaty failed by six votes of getting the necessary two-thirds; twenty-odd Democrats who were ardently for the treaty voted against it, because of the reservations. As with the League of Nations, the importance of the French Security Treaty was not realised at Paris in the making of the peace. It has been the crux of nearly all the troubles which have beset Europe since the Armistice was signed on Nov. 11 1918. If the French had been assured of protection, their attitude toward Germany, toward reparations and toward disarmament undoubtedly would have been more in keeping with the public opinion of the world. (See SECURITY.)

It is only in retrospect that historic events are seen at their just value. Those who are making history oftentimes exaggerate the importance of some things and underestimate the importance of others. At Paris undue stress was laid on questions of enemy disarmament and reparations—both matters of temporary interest and susceptible of quick solution. Within a few decades they pass from view; but questions like the League of Nations and the security of France reach to the heart of peace and war, and are vital if Western civilisation is to live. It has taken Europe seven long years to realise this. If it had been seen at Paris, untold hardships might have been averted. The heavy losses incurred by the Allies during the War blurred, in a way, their sense of proportion. They could not realise that the costs of victory were so great that it was impossible to make the conventional treaty of peace, awarding to themselves damages and territories which might measurably recompense them for the sacrifices made. It was a time to forget rancour and to strive to make another such holocaust improbable and remote. If such a treaty had been framed at Versailles, the years following the War indicate that it would have been more satisfactory and profitable than the one actually made.

The so-called Secret Treaties were mischievous elements in making decisions, particularly regarding the Italian frontier. Great Britain and France entered the conference with their hands tied by promises made to Italy in order to induce her to enter the War on the side of the Allies. The United States was

free to act as seemed best, but even so the task proved beyond her capabilities. Few, if any, disinterested observers believed that the Tyrol as far north as the Brenner should have been wrenched from Austria under the pretext of making safe Italy's northern boundaries.<sup>1</sup> Italy's claim to Trieste and to some islands of the Adriatic was much clearer. The fight between Wilson on the one hand and Orlando and Sonnino on the other produced the most acute crisis of the conference. The Yugoslavs were ill-advised in not meeting the concessions the Italians were ready to make. They were counting on Wilson's coercing Orlando and Sonnino, but they failed to reckon on what might happen if the Peace Conference adjourned without a settlement being reached. The breaking-point came when Wilson gave out his statement of April 23 1919. This infuriated the Italians and they left Paris with the threat never to return. Wilson bore the brunt of the criticism which this rift in the conference caused, but he was by no means solely responsible. He was encouraged to do what he did do by members of both the French and British delegations.

*Shantung.*—At this moment feeling regarding Shantung ran high. No direct threat was made by the Japanese delegates, but it was in the air that if the conference refused their request they too would withdraw. They did not ask to keep Shantung, but merely that it should be returned to China through them. Here again Wilson bore the brunt of the fight, and the taunts of the liberals throughout the world were levelled at him. Even his associate commissioners from the United States, with the exception of Col. Edward M. House, protested against his acceding to the Japanese request. However, he and House had personal assurance from Baron Makino and Viscount Chinda that the province would be returned. They were men of the highest character and integrity, and their word, which has since been fully kept, was accepted without question, much to the chagrin of the Chinese commissioners.

The Chinese were advised by House to accept the decision in good faith and to compliment the Japanese upon their willingness to place the matter on such a high moral plane, thus marking a new era in international obligations. But they refused this advice. The bitterness of their defeat made them resentful and they gave notice that they would not sign the treaty; and they did not. The Belgians also were dissatisfied at this period of the conference. Suggestions of withdrawal were made and, with Italy gone, for the moment at least, it would have been fatal to the conference if Japan had left because her pledged word to restore Shantung to China was not accepted. It was a critical period of the conference, and the subsequent action of Japan has shown the wisdom of meeting her request.

*The Saar Valley.*—The demand of the French for the Saar Valley came rather late in the proceedings and was at first offered timidly. They tried to present an historical claim to it, but finally based their arguments upon the justice of their case. The Germans had wantonly wrecked the coal-mines of north-eastern France and, it was said at the time, had rendered them useless for a long period of years. The extent of the damage has since been proved not to be so great as was first estimated, but it was sufficient to warrant a modified yielding to the French claim. The difficulty was to arrange it in a way not to do violence to the almost wholly German population of the territory occupied. That it has worked out so well is due to the sagacity of the French in placing in charge engineers and officers who speak German fluently. Another helping factor was the superior value of the franc over the mark during the first trying period of occupation. For a time the German workmen in the Saar mines received on this account a much greater compensation for the same work than their fellow-miners in other parts of Germany.

*Self-Determination.*—During the War, when President Wilson announced his theory of self-determination, it stirred the dor-

mant hopes of many peoples and did much to break the discipline in the Central Powers behind the lines. This declaration of our War aims brought to Paris many and diverse delegations from Europe, Asia and Africa. They were the most picturesque as well as the most ill-informed and unreasoning of all those who gathered around the historic centre where the peace was made. This noble sentiment, carried to its logical conclusion, would have wrecked the governmental machinery of the world. The conference has received unjustified blame for dividing up the Austrian Empire, but it must be remembered that the empire had already fallen apart before the Peace Conference met. The questions which came before the conference involved the boundaries of states in process of formation, and not the creation of such states themselves. Had the conference undertaken to curb the demand for national independence, its authority to do so would have been denied and another war would have begun—a war springing from the bowels of the old one and even more fierce and bitter. What was done had, of necessity, to be done. There was no other way. No such human upheaval as occurred during the years 1914-8 could be composed in exact justice to all—and that it was not done in this instance is no matter of surprise.

*The Polish Frontiers.*—The delineation of the frontiers of the new Poland was a task fraught with the gravest dangers, both for the moment and for the future. The reason for this was that her still great and powerful neighbour, Germany, was forced to yield a considerable part of her territory in order that there should be a national Poland and, further, that she should be given an outlet to the sea. Germany has never been reconciled either to Silesian boundaries or to the corridor to Danzig. She gave up the rich provinces of Alsace and Lorraine with scarcely a murmur, for when the tide of war went against her she realised that one of the penalties of defeat would be the restoration of territory taken from France in 1871. But the losses on her eastern frontier came as a shock, and cut deep into her national pride and consciousness. It may be that in time, and with wise and considerate treatment on the part of Poland, an adjustment of their differences may be reached. It is not an insoluble problem, but it is one that calls for patience and a high order of statesmanship. With better trade relations between the two countries and with Germany in the League of Nations, there may come a feeling of mutual dependence; and a yielding here and there by each may accomplish the miracle.

The rectification of the Belgian-Prussian frontier was a matter less serious, but the gain to Belgium is so slight that some day Belgium may feel it to be good policy to return to Germany the Prussian part of Moresnet as well as Eupen and Malmédy. While this district has some forests of value, there are less than 75,000 people involved, and their voluntary return to Germany would be a *beau geste* which would yield a far greater return in goodwill.

*Mandates.*—The acceptance of the principle of mandates was one of the most far-reaching decisions of the conference. It was a new venture in the government of backward peoples, and one destined to play a large part in the affairs of many nations. It gave an excuse and a method for taking over the German colonies by the several countries interested. The German colonial empire, built up painstakingly and at great cost, vanished overnight. It was one of the hardest blows which her national pride received, and one which she resents with passionate fervour. So strong is this feeling in the Germany of to-day that even some of the French are seriously considering the advisability of giving Germany a mandate over a part of the lost territory. The British protested during the War that they desired no new territory, but the insistence of South Africa, Australia and New Zealand made it impossible not to heed their demands. All of these countries resented the implied threat which the retention by Germany of her colonies might prove to be. Japan and France were equally determined, with the result that the vast colonial estate, which lay chiefly in Africa, was divided between the claimants according to their geographical situation.

<sup>1</sup>This is true with regard to the northern part of the region, South Tyrol, but many disinterested observers believed that the remaining and larger part, the Trentino, emphatically Italian, should be transferred to Italy.—Ed. E.B.

The policy of control based on mandates is a new departure in international polity; it involves the recognition that all nations have economic and other interests in backward regions. Until now, backward countries generally have been controlled or exploited by some Power for its own selfish purposes, and the good that has come from such control or exploitation has been merely incident thereto, and where a single control has not existed, backward communities have been a constant source of friction between the more civilised states, because of a desire to obtain control of their resources; this friction has oftentimes resulted in war.

Until the Paris Conference there had been no attempt to reach a general understanding or fixed policy between the more powerful civilised nations regarding the control or betterment of such states or territories. However, the system hitherto practised was admittedly so bad that when the conference came to the disposition of the late German colonies, there was general agreement that a more enlightened policy should be inaugurated. In furtherance of this desire Article 22 was incorporated in the Covenant of the League of Nations, and subsequently a commission was appointed to sit in London during the summer of 1919 for the purpose of preparing the terms of the mandates. Upon this commission were Lord Milner, who had as his adviser Lord Robert Cecil; M. Simon, French Minister for the Colonies; Viscount Chinda of Japan; Signor Marconi for Italy; and Col. House for the United States, with Mr. George Louis Beer as adviser (see MANDATES).

The acceptance by the members of the League of Nations of this new principle, in the difficult matter of the control of backward countries, was a long step forward. A mandatory Power was to accept trusteeship, not for the benefit of itself but for the benefit of the natives, and, incidentally, to permit other countries to share in the development of the state over which it exercised the mandate. The fact that hereafter each Power holding such a mandate will be under close observation will have a tendency to promote the best administration possible. The report which must be given each year to the Council of the League will in itself stimulate rivalry, and the Power giving the best account of its stewardship will be the one to hold the highest place in the esteem of the world.

**BIBLIOGRAPHY.**—The standard history of the Peace Conference is *A History of the Peace Conference in Paris*, 6 vol., ed. H. W. V. Temperley (1920-4). It is written chiefly by British experts, many of whom took part in the conference, but its point of view is objective. The texts of the treaties are to be found in the *Treaty Series* of the British Foreign Office, published by H. M. Stationery Office (1920). There is a special volume, *The Treaty of Peace between the Allied and Associated Powers and Germany (with amendments) and other Treaty Engagements Signed at Versailles June 28 1919, together with the Reply of the Allied and Associated Powers to the Observations of the German Delegation on the Conditions of Peace* (1925). *Comments by the German Delegation on the Conditions of Peace and the Reply of the Allied and Associated Powers* are published by the American Association for International Conciliation (1919) and the covering letter in the *American Journal of International Law* (July 1919). See also *Deutscher Geschichtskalender, Vom Waffenstillstand zum Frieden von Versailles*, pp. 565 seq. (Leipzig, 1918).

Important confidential documents are contained in R. S. Baker, *Woodrow Wilson and World Settlement* (1922). Important memoirs have been written by participants in the Peace Conference, especially André Tardieu, *The Truth about the Treaty* (1921); B. M. Baruch, *The Making of the Reparation and Economic Sections of the Treaty* (1920); Robert Lansing, *The Peace Negotiations* (1921); see also J. M. Keynes, *The Economic Consequences of the Peace* (1920); E. M. House and C. Seymour, *What Really Happened at Paris* (1921); a series of essays written by American delegates, (E. M. Ho.)

### VIII. LATER CONFERENCES IN PARIS

After the conclusion of the important conference already described, three meetings of Allied statesmen were held in Paris to consider matters arising out of the execution of the Treaty of Versailles.

**Jan. 24-30 1921.**—A meeting to consider proposals put forward by Allied experts as a result of a meeting between them and German experts at Brussels from Dec. 16-22 1920, in continuation of the Conference of Spa (see SPA, CONFERENCE OF).

The Allied statesmen adopted the experts' proposal for two German annuities, one fixed and the other on a sliding scale, but they proposed to saddle Germany with a far heavier burden than the experts had considered reasonable. The Allied Govts.' proposals as formulated by their representatives at Paris were rejected by Germany.

**Aug. 8-13 1921.**—A meeting of the Supreme Council of the Allied Powers to take action upon the results of the plebiscite in Upper Silesia (see SILESIA, UPPER). After failing to agree upon a line of partition between Germany and Poland, the representatives of the principal Allied Powers decided unanimously to refer the question to the Council of the League of Nations, under Article 13 of the Covenant. The Council accepted the task, and eventually made a recommendation which was adopted by the Conference of Ambassadors (see AMBASSADORS, CONFERENCE OF). This was the first case in which action arising out of a peace treaty, which fell within the province of the Ambassadors' Conference and of the Supreme Council as their principals, was transferred to the League of Nations by common consent. At this conference the Allied statesmen also considered the Greco-Turkish War in Anatolia, the Russian famine and several questions relating to Germany. In particular it decided that the additional occupation of territory carried out during the preceding March should continue, but that the economic sanctions taken simultaneously should be removed (see LONDON, CONFERENCE OF, Feb. 21-March 14 1921).

**Jan. 2-4 1923.**—A meeting between Allied statesmen to consider the terms on which Germany might be granted a reparations moratorium—terms on which agreement had already proved impossible at the London conferences of Aug. and Dec. 1922 (see LONDON, CONFERENCE OF). Since the adjournment of the latter of these conferences the situation had been rendered much more critical by the momentous decision which the reparation commission had taken on Dec. 26 1922, when a majority of the commission, consisting of the French, Belgian and Italian delegates, with the British delegate in a minority of one, had formally declared Germany in default in respect of deliveries of timber. Backed by this decision, M. Poincaré repeated with greater vigour the proposals which he had made on the two occasions aforementioned. In return for the remission of the French war debt to Great Britain, he would only be willing to cancel an equivalent amount of German "C" bonds, and in return for granting a moratorium to Germany there must be a military occupation of the Ruhr and a seizure of "productive pledges" in the form of coal deliveries, the seizure of the coal-tax hitherto payable by the industry to the German Govt. and the requisitioning of timber and other raw and manufactured products in the occupied territory.

On the other hand, the British Govt. proposed that Germany should be given an absolute moratorium for four years (except for certain deliveries in kind which were to be credited against future payments), on condition that Germany should stabilise the mark on lines suggested in the majority report of a commission of international experts which the German Govt. had called in during the preceding autumn; and secondly, that Germany should accept financial control by a foreign finance council, of which the German Minister of Finance was to be chairman, *ex officio*, and which was virtually to supersede the reparation commission. In regard to inter-Allied debts, the British Govt. made specific proposals which would have given substantial relief to France in exchange for a remission of German indebtedness to France, which would have been equally substantial.

The gulf between these two sets of proposals was so great that there was no chance of an accommodation, and the conference broke up on Jan. 4 after the French and British Govts. had "agreed to disagree." A week later, on Jan. 11 1923, the French and Belgian armies invaded the Ruhr (see REPARATIONS).

(A. J. T.)

**PARIS, UNIVERSITY OF** (see 27.751).—The University of Paris has prospered greatly under the constitution given to it in 1806 by the forceful genius of Louis Liard, and in all its faculties and departments receives an increasing number of foreign students

A university quarter has been created in addition to the numerous separate buildings in various parts of Paris, with the Palais de la Sorbonne as the main centre, where are housed the faculties of science and letters, the university library and the national school of charters. For other purposes an excellent site has been made available by the wise generosity of the city of Paris, on which, with the funds given by Émile Deutsch de la Meurthe, further provision is made for the accommodation of French students resident in Paris. The demolition of the fortifications has thus afforded the university the space it needed so much.

Other notable benefactions to the university have been made by the Marquise Aremati Visconti, M. Blumenthal, MM. Solvay et Cie, Dr. Kaprak of Bombay, Baron Mitsui and other Japanese notables, the Republic of Czechoslovakia, MM. Otto Kahn, Masson and Lavissee. L'Institut du Radium et Fondation Curie has received precious gifts from the Rothschilds, from public funds, from the Franco-Anglo-American League against cancer, and from Lazard Frères and La Filiale Canadienne de la Fondation Curie. Bequests of a valuable nature have been made to the faculties of medicine, science, letters and pharmacy; while with the purpose of aiding and stimulating scientific research—for public ends and for the welfare of individuals—many important developments have been effected in which the University of Paris, true to its ancient tradition, has taken a leading part.

*Collège de France* (see 27.769).—The great reputation of this foundation has been maintained worthily—even enhanced—since 1910 by periodical revision and reorganisation in order to meet the specialised needs of advanced students of both sexes in the higher branches of scholarship and science, and by the institution of new chairs from time to time. The newer chairs are those in human geography, public assistance, economics of Algeria, co-operative studies, colonial history and colonial protistology and pathology, some of which owe their existence to public sources and others to private benefactors such as Albert Kahn.

**PARKER, ALTON BROOKS** (1852–1926), American lawyer, was born at Cortland, N.Y., May 14 1852. He studied at the local academy and normal school, taught for a short time, read law and graduated from the Albany Law School in 1873. Admitted to the bar he began to practise at Kingston, N.Y., and in 1877 was elected surrogate of Ulster co., being re-elected in 1883. He resigned in 1885 on being appointed by the governor justice of the N.Y. Supreme Court to fill a vacancy, and the following year was regularly elected. He was a delegate to the Democratic National Convention in 1884 and in 1885 declined President Cleveland's offer of the first assistant postmaster-generalship. He was appointed a member of the second division of the N.Y. Court of Appeals in 1889 and a member of the general term in 1893. In 1898 he was elected Chief Justice of the N.Y. Court of Appeals. In 1904 he resigned on being nominated by the Democrats for president, but he was defeated by Theodore Roosevelt, the electoral vote being 336 for Roosevelt to 140 for Parker, the popular vote 7,623,486 for Roosevelt to 5,077,971 for Parker. He then resumed the practice of law in New York City. He was a delegate-at-large from New York to the National Democratic Convention in 1912. In 1913 he was counsel for the managers of the impeachment of Governor Sulzer of New York. He died in New York City May 10 1926.

**PARKER, HORATIO WILLIAM** (1863–1919), American composer and musician, was born at Auburndale, Mass., Sept. 15 1863. He studied music first in Boston, but later attended the Royal Conservatoire at Munich. On his return to America in 1885, he became professor of music in the Cathedral School of St. Paul, Garden City, Long Island. From 1888 to 1893 he was organist of Trinity Church, New York City, and from 1893 to 1901 organist of Trinity Church, Boston. In 1894 he was appointed professor of the theory of music at Yale. His oratorio *Hora Novissima* was widely performed in America. It was also given in England in 1899 at Chester and at the "Three Choirs" festival at Worcester, the latter an honour never before paid an American composer. His opera *Mona* won the Metropolitan

Opera Company's \$10,000 prize in 1911 and in 1914 his opera *Fairyland* gained a prize of the same amount offered by the National Federation of Women's Clubs. His cantata *Morven and the Grail* was written in 1915 for the centenary celebration of the Handel and Haydn Society of Boston. His other works include the cantatas, *King Trojan* and *The Kobolds*, the oratorios, *St. Christopher* and *A Wanderer's Psalm*, besides numerous sacred and secular pieces. He died at Cedarhurst, Long Island, Dec. 18 1919.

**PARKIN, SIR GEORGE ROBERT** (1846–1922), British educationist (see 20.831), published in 1912 *The Rhodes Scholarships*, an account of his works as organising representative of the Rhodes Trust (see 23.257). He was knighted in 1920 and died in London June 25 1922.

**PARRY, SIR CHARLES HUBERT HASTINGS** (1848–1918), British composer (see 20.865), retired from his professorship at Oxford in 1908. He died at Rustington, Sussex, Oct. 7 1918, and was buried in St. Paul's Cathedral, London.

**PARSONS, SIR CHARLES ALGERNON** (1854– ), British engineer, was born in London June 13 1854, the fourth son of the 3rd Earl of Rosse. Educated privately and at St. John's College, Cambridge, he entered the Armstrong Works at Elswick in 1877. In 1884, having served for a year on the experimental staff of Messrs. Kitson, of Leeds, he entered into partnership with Messrs. Clarke, Chapman and Co., of Gateshead. On the dissolution of the partnership in 1889, Parsons, whose invention of the Parsons steam turbine was bringing him into considerable prominence, established his own works at Heaton, Newcastle-upon-Tyne, for the manufacture of steam turbines, dynamos and other electrical apparatus (see 25.845). Besides the chairmanship of C. A. Parsons and Co., he occupied important positions on the directorate of various electrical supply and engineering companies. He was made F.R.S. in 1898, was awarded the Royal Society's Rumford medal in 1902, was president of the Institute of Marine Engineers 1905–6 and of the British Association 1919–20. In 1911 Parsons was created K.C.B. In 1884 he married Katherine, daughter of William Bethell.

**PARSONS, WILLIAM BARCLAY** (1859– ), American engineer, was born in New York City April 15 1859. He graduated from Columbia University (A.B., 1879; C.E., 1882). At first he entered the service of the Erie Railroad, but resigned to take up general practice in New York City in 1885 as consulting engineer. He became deputy chief engineer in 1891 to the Rapid Transit Commission of New York City and was chief engineer of the commission 1894–1904. As such he designed and supervised the construction of the first part of the subway system there. He has been connected professionally with railway construction in various parts of the world, especially China. He was a member of the Isthmian Canal Commission, 1904; advisory engineer to the Royal Commission on London Traffic, 1904; a member of the board of consulting engineers of the Panama Canal, 1905; and chairman of the Chicago Transit Commission, 1916. He served during the Spanish-American War as chief of the engineers, National Guard of New York, and in the World War was Major and later Colonel of the 11th U.S. Engineers attached to the B.E.F. and A.E.F. in France.

His publications include *Turnouts* (1885); *Track* (1886); *Rapid Transit in Foreign Cities* (1895); *An American Engineer in China* (1900); *The American Engineers in France* (1920); *Robert Fulton and the Submarine* (1923).

**PARSONS, WILLIAM EDWARD** (1872– ), American architect and city planner, was born at Akron, O., June 19 1872. He graduated at Yale University in 1895 and Columbia University in 1898, where he was awarded the McKim fellowship in 1899, attending the École des Beaux Arts, Paris, and studying under Laloux. He entered the office of J. C. Howard, architect, New York City, in 1901, and was appointed consulting architect to the U.S. Govt. in the Philippines, 1905. He designed many public and other buildings in the Philippines, including the Manila Hotel, Philippine General Hospital, the University Hall, the Manila Club and the Manila Normal School. He also developed and directed the execution of a number of city plans,

including those for Manila, Baguio and Sebu, and instituted the conservation of the old fortifications of the city of Manila as public parks. He resigned in 1914 and returned to the United States, opening practice in Chicago in 1919 with E. H. Bennett as partner. The firm was retained to prepare plans for municipal improvements and town-planning in many parts of the United States, including Chicago, Buffalo, St. Paul, Pasadena and San Juan, Porto Rico.

**PASCAL, JEAN LOUIS** (1837-1920), French architect, was born in Paris June 4 1837, and at the age of 16 became a pupil of Gilbert. Later, when in the studio of Questel, he entered the École des Beaux-Arts, and amongst other distinctions gained the *Grand Prix de Rome* in 1866. On his return to Paris in 1870, after his four years at the Villa Medici, he was appointed inspector of works at the Louvre and the Tuilleries. In 1872 he became patron of his *atelier*, and thereafter was appointed assessor in public competitions, and subsequently received many distinctions. Amongst these was his election to the council of the Beaux-Arts and president of the jury, and to membership of the Institut de France, and finally he became *commandeur de la Légion d'Honneur*. In his long career the private, as apart from official, work of Pascal was of a very diversified nature, and covered a wide area of ground, domestic and civil, and particularly a long series of artistic memorial monuments such as those commemorating Col. d'Argy at Rome, Henri Regnault at the École des Beaux-Arts and President Carnot at Bordeaux.

Among Pascal's buildings are the Château du Doux, Corrèze, that for the Faculté de Médecine, Bordeaux—a design with much dignity and calm—the painter Perrault's house and studio, Paris, and several villas and châteaux in the provinces—at Pau, Beaulieu, Avignon and elsewhere. He lived long enough to see, at the close of his busy career of over 50 years, the completion of the Bibliothèque Nationale, Paris, a fine building characteristic of his learning and ingenuity. With M. Gaudet, he is responsible for the splendid edition of Blondel's *Architecture Française*, published under the auspices of the French Government. The celebrated *atelier* of which he was for so many years the patron was responsible in his time for the training of many architects to be found later on in every country in Europe, in the United States and in Canada. Among them were Sir John Burnet, Thomas Hastings of New York, Signor Beltrani of Milan and Henri Nénot of Paris. In 1914 he was awarded the gold medal of the Royal Institute of British Architects, but his great age and state of health prevented his receiving this in person. He died in Paris in 1920.

**PASCOLI, GIOVANNI** (1855-1912), Italian poet, was born at San Mauro di Romagna Dec. 31 1855. After studying at the college of the Scolopi fathers at Urbino, he won a scholarship which enabled him to enter the University of Bologna. There he obtained his degree in literature and was afterwards appointed secondary school teacher successively in Bologna, Massa and Leghorn. He soon began to acquire a reputation as a poet, and in 1891 published his first volume of verse, *Myricae*. After he had won the prize for Latin verse at Amsterdam, he was appointed to the chair of Latin and Greek grammar at the University of Bologna, whence he was transferred first to Messina and then to Pisa as professor of Latin literature; finally he was recalled to Bologna to succeed the poet Carducci as professor of Italian literature, an appointment which he held until his death. He published several other volumes of poetry, *Primi poemetti* (1912), *Nuovi poemetti*, *Canti di Castelvecchio*, *Poemi conviviali*, *Poemi del Risorgimento*, *Canzoni di Re Enzo* (1908) and *Carmina* (in Latin). Pascoli was a mystic, given to meditation and solitude, and his poetic output faithfully reflects the characteristics of his melancholy and extremely sensitive temperament. He died at Bologna April 6 1912.

See A. Galletti, *La poesia e l'arte di G. Pascoli* (1918); J. J. Hartman, *De Joanne Pascoli poeta Latino* (1920); F. Morabito, *Il Misticismo di Giovanni Pascoli* (1920); A. Valentin, *I Pascoli, Les thèmes de son inspiration* (1925).

**PAŠIĆ, NICHOLAS** (1846- ), Serbian statesman, was the son of a merchant at Zajčear, close to the Bulgarian frontier. He

studied engineering first at Belgrade and then, with the help of a State bursary, at the University of Zürich, where he and other young Serbs came under the influence of the Russian revolutionary Bakunin. Where they differed so profoundly from him was in their insistence upon nationality and national liberation as an essential preliminary to all social progress. Pašić was one of a small group of remarkable men who surrounded Svetozar Marković, and on the latter's early death in 1875 became one of the chief exponents of his views, which were of capital importance for the political development of Serbia. He became a deputy in 1878, and was in 1881 one of the founders of the Radical party. Its ambitious programme of constitutional and administrative reform, freedom of the Press and of assembly, and in foreign affairs national unity and a Balkan alliance, brought the party into acute conflict with the reactionary régime of King Milan.

A popular rising which broke out in the Timok district in 1883 led to the arrest of most of the Radical leaders and fresh repressive measures. Pašić fled across the Danube and was condemned to death *in absentia*, remaining in exile till after King Milan's abdication in 1889. On his return he became president of the Skupština and on two occasions mayor of Belgrade. He was Premier for the first time from Feb. 1891 to Aug. 1892, and as Foreign Minister accompanied the young King Alexander on his first visit to the Tsar. As a strong Russophile he was made Serbian Minister in St. Petersburg (Leningrad), but resigned as a mark of protest against the illegal return of King Milan to Serbia in 1894. The Radicals were now in keen opposition, and when an attempt was made on the ex-king's life in 1899 the Government rid itself of their leaders by trumped-up charges of engineering the crime, and imposed savage sentences of forced labour. Pašić, thanks to Russian remonstrances, only received five years and was then amnestied on condition of leaving the country. He only returned after Milan's final withdrawal.

After the fall of the Obrenović dynasty in 1903 the Radical party became dominant, and Pašić was Foreign Minister in 1904 and Premier in 1906 and again from 1908-10. He shared in Milovanović's negotiations for a Balkan League and on his premature death in 1912 became the dominant figure in the Radical party, resuming the Premiership on the very eve of war with Turkey. He remained in office throughout the two Balkan wars, and contributed materially towards the alliance with Greece and the rapprochement with Rumania. While his foreign policy was essentially Russophile, he, on two occasions, in 1912-3 made overtures to Vienna, which Berchtold contemptuously rejected. Discontent inside his own party had led to an important secession, and in the spring of 1914 he was engaged in an acute struggle against the Opposition and had to promise a revision of the constitution.

Parliament had already been dissolved and the electoral campaign started when the murder of the Archduke at Sarajevo brought the already strained relations with Austria-Hungary to a head. But so absorbed was Pašić in internal politics that he was absent from Belgrade when the fateful ultimatum was presented, and even then was preparing to visit Veniseles at Salonica when an urgent message recalled him. Party discord was silenced by the national danger, the elections were postponed and the already dissolved Parliament reassembled at Niš. In Nov. a coalition Cabinet was formed, but Pašić remained Premier, and when in 1917 the Opposition again seceded, he once more formed a purely Radical Government.

In foreign policy he had always relied implicitly on the support of Conservative Russia, and the revolution of March 1917 and the fall of Tsardom weakened his position both at home and abroad. He thus saw himself forced to recede from the strictly Pan-serb and Orthodox attitude which he had taken up, and to negotiate, upon equal terms, with the Yugoslav committee under Dr. Trumbić, the so-called "Declaration of Corfu" (July 1917), which laid down the broad lines of the future unified Yugoslav State. But his relations with the Committee became increasingly strained, and he stubbornly denied to them any status in the allied camp and refused to admit them to a coalition Cabinet.

This attitude was the main reason why the Entente governments withheld from the Yugoslavs that recognition which they accorded in Aug. 1918 to the much less favourably situated Czechoslovaks. The result was that Austria-Hungary collapsed before any agreement had been reached among the Allies on the Yugoslav problem, and that Italy, abandoning the compromise reached at the Roman Congress of Oppressed Nationalities in the previous April, reasserted her full territorial claims under the secret Treaty of London. Despite this dangerous situation Pašić maintained his obstructive tactics not merely towards the Yugoslav committee but also towards the new provisional Government which had been formed in Zagreb and which had at once nominated Trumbić as its spokesman in Paris. Finally, a certain compromise was reached, and while Protić became the first Premier of Yugoslavia, Pašić was made first delegate to the Peace Conference, with Trumbić and Vesnić as his colleagues.

During the first two years of the new State he remained under a partial eclipse, but on his return to Serbia soon reasserted his ascendancy over the Radical party and strengthened its machinery and discipline, as against the loosely knit Democratic party. The first general elections held after the World War (Nov. 1920) gave no party a majority and rendered complicated bargaining inevitable. This situation gave such a superb tactician as Pašić the chance for which he had known how to wait. In Jan. 1921 he again became Premier, and thanks partly to his skilful bargaining with the minor groups and partly to the foolish abstention of the Croat Peasant party, he was able to manoeuvre the new Centralist constitution through Parliament (June 28 1921), and as reprisals for the attempted murder of the Prince Regent and Pašić and for the successful murder of Drašković a month later, to suppress altogether the Communist party. In the following winter he was able to manoeuvre his Democratic allies out of the Government and to form a purely Radical Cabinet. At the elections of March 1923 he failed to secure a majority, but was again saved from an untenable position by the refusal of Radić and his party to enter Parliament and join the rest of the Opposition in overthrowing Pašić. The blunders of his enemies, even more than his own remarkable skill and endurance, rendered him almost indispensable, and though from July to Oct. 1924 he had to give place to a coalition Cabinet under Davidović, he returned to power stronger than ever.

In Feb. 1925 he again dissolved Parliament, threw Radić and his colleagues into prison, and by the adoption of extremely drastic electoral measures secured a small working majority. On this Radić made a complete surrender of his republican, federalist and anti-militarist principles, acknowledged the dynasty and the "Vidovdan" constitution, allowed his deputies to take their seats in Parliament and accept portfolios, and finally, in Oct. 1925, himself entered the Cabinet as Minister of Education. Thus Pašić's tactics of violence successfully overcame the long Croat resistance which had so gravely retarded the consolidation of Yugoslavia and produced for the time an irresistible union of the two strongest parties in the country.

(R. W. S.-W.)

**PASTRNEK, FRANTIŠEK** (1853- ), Czech philologist, studied in Vienna, where he qualified in 1888 as a lecturer on Slavonic philology by his work entitled *Beiträge zur Lautlehre der Slavonischen Sprache in Ungarn*. From 1895 onwards he was a professor of the same subject at the Charles University in Prague. He published many articles and reviews in native and foreign periodicals dealing with Slavonic philology. Among his works may be mentioned *The Slavonic Apostles Cyril and Methodius* (1902). He compiled a bibliographical survey of Slavonic philology between 1876 and 1891. He also made a study of various Slavonic dialects (*cf. Zur Charakteristik der mährischen Dialekte*, Archiv. fur slav. Phil. XX. 1898).

**PATERSON, N. J.**, U.S.A. (see 20.912), increased its population to 135,875 in 1920, of whom 45,242 were foreign-born, and to 141,695 in 1925 (census bureau estimate). The output of its factories was valued at \$69,263,000 in 1909; \$216,659,000 in 1919; and in 1923, recovering from a drop of 25% in 1921, at

\$194,857,975, two-thirds being contributed by silk manufactures (\$112,100,378) and the dyeing and finishing of silk and other textiles (\$20,386,475). Paterson dyes 75% of the silk that comes into the United States and makes 20% of the country's output of broad-silk, in plant units ranging from 10 to 750 looms.

By 1925 Paterson had made substantial progress on a programme for modernising its public school plant. A high school for girls, to be opened in Feb. 1926, was built on a seven acre tract in the heart of the city. By joint action on the part of Paterson and other cities in the Passaic river valley, a trunk sewer was constructed, at a cost of \$22,000,000, to carry the sewage of the valley out to Robin's Reef in New York Bay (opened 1924). In 1925 a museum was established in connection with the public library; and a series of lecture courses, called the Paterson collegiate centre, was inaugurated by the chamber of commerce in co-operation with New York University. Work on the elimination of grade crossings on the Erie Railroad was begun in 1924. A city plan commission and a zoning commission were in operation, and in 1926 Paterson was co-operating with other municipalities in a project for securing its own water supply.

**PATHOLOGY.**—The study of pathology began about 100 years ago and it was in the last 30 years of the 19th century that its importance began to be recognised by definite and separate academic provision for its prosecution. At first it consisted mainly of the investigation of the changes found in the human body after death and their correlation with the signs of disease which had been observed during life.

The large progress made along these lines soon led to its expansion in a variety of directions until pathology came to include almost anything which had to do with disease, and its field included aetiology, pathogenesis, morbid anatomy, microscopic histology, parasitology, functional changes, chemical alterations, and indeed any topic, except diagnosis and treatment, which was open to fairly accurate study. The contemporary progress of medicine and surgery showed also that laboratory methods for the investigation of sick persons afforded valuable aids in diagnosis, this large subject of "clinical pathology" is properly recognised as belonging to clinical medicine rather than to pathology.

This very diverse assemblage of studies forms together a consistent whole, which necessarily suffers by sub-division, but the increase of knowledge in some directions has been so great that it is no longer practicable to treat the various sections as a single discipline, and bacteriology, immunology, protozoology, pathological chemistry and other branches have been progressively separated as specialised topics each with its own devotees, literature and academic staff. It remains here to consider what progress has been made since 1910 in the residuum which still remains under the heading "pathology." Advance here has been relatively small; apart from a tendency to assimilate pathology to the other biological sciences and a considerable increase in the attention paid to functional as distinct from anatomical changes, no ideas or methods of primary importance have emerged to cause any great change in general outlook, and workers have mostly been engaged on the elaboration and consolidation of the position represented by the article in the 11th edition (see 20.913). Pathology in its restricted sense may be taken to mean the study of the reactions of living organisms to injury—the investigation, that is, of what the body does in response to abnormal conditions and circumstances imposed upon it.

**Nature of Injury.**—The injury may be of very various kinds: mechanical trauma, injury by poisonous substances (many of the most important of which are produced by parasites), defective supply of food (e.g., by living at high altitudes or by errors of diet), electricity, radiation energy and other factors which are still indefinite. The injury may immediately cause gross alterations in structure, and it is known that the physical injury of a cell often entails radical changes in the biological and chemical characters of its protoplasm which depend in some way on its architecture as a whole. Or the injury may be anatomically perceptible though unaccompanied by any large structural changes. Or it may, like electric shocks, cause no visible change and yet lead to a complete and permanent cessation of the activities

which constitute what we know as life. Or, finally, it may cause no anatomical changes recognisable by present methods and be put in evidence only by greater or smaller alterations in function.

The obvious anatomical changes in injured tissues with which the early students of pathology mostly concerned themselves are not as a rule the direct and immediate consequence of the injury. They result partly from alterations which take place in cells after death by the process known as *autolysis* and partly from the activity of the uninjured and healthy cells in the neighbourhood and elsewhere in the body which constitutes the response or *reaction*.

*Autolysis*.—This is the mechanism by which dead tissues tend to be automatically removed. The normal body consists of life-cells and certain products of live cells (such as bone) which are not wholly dead in that they are in functional relation to living tissues. Any dead cells constitute therefore abnormal or foreign elements and it is required to remove them if restoration of the normal structure is to be achieved. When cells die, ferments are set free which act on the substance of the cell much in the same way as the digestive juices act on food in the alimentary canal. The solids are liquefied and so readily absorbed into the circulating blood, carried away to other parts of the body and if necessary, excreted. Autolysis is naturally signalled by substantial structural changes recognisable naked-eyed or by the microscope. The translucency, colour and consistency of the part are altered, and it is on the recognition of these secondary changes that morbid anatomists depend. Under the microscope the nuclear membrane and chromatin, the protoplasm and the cell wall become more and more disorganised until nothing remains except amorphous débris.

The *reaction* by the uninjured parts of the body is the means by which the effect of the injurious agent is diminished and the normal constitution of the injured part restored as far as may be possible. It may be local or general. Many of the symptoms and signs of disease are due to it rather than to the injury which is the beginning of the disease.

*Cellular Processes*.—In the higher animals, cells which are mechanically injured or which have suffered gross structural change seem as a rule to be incapable of recovery: nerve cells may have their long processes cut off and be able to repair the damage, but such facility is quite exceptional. It is more frequent in lower forms of life but here, too, in unicellular animals such as bacteria any substantial injury is usually irrecoverable and is made good not by the restoration of the individual but by a compensatory increase of the other members of the community of which the injured cell formed a part. Similarly in man, when a part is injured, the whole of the body is available and may be used in co-operation to bring the part, and with it the whole, back to normality. This reaction, whatever its real nature, has the appearance of being purposive in the sense that it is adapted to achieve a definite end.

Pathological changes indeed illustrate exquisitely two great biological truths. The first is that it is characteristic of all live organisms to resist any alterations in their structure and composition and, if these are varied by circumstances which are beyond control, to proceed actively to correct the deviation and so return to the normal state. The second is that all the parts of which the organism is composed work together and in relationship to one another for the common good. A growing realisation of these principles has been one of the most productive changes in recent pathological thought. It carries the corollary that the anatomical changes, which are generally the first objects of study, must be regarded as representing phases of processes rather than definitive states. The mode of thought which has collected into museums specimens of morbid anatomy and classified them as if they were species of animals should be replaced by one which regards a hypertrophied heart, a cirrhotic liver, or a sclerosed kidney, not as a "typical" example of a state, but as an illustration of one stage in a process by which the body has responded to a stimulus of injury.

*Mechanism of Reaction*.—The general nature of the reaction being purposive and restorative, it is likely that the particulars

of the mechanism by which it is brought about will vary widely, since the constants of live organisms are the ends which are achieved rather than the means by which they are reached. Such is the case as will be seen from some illustrative examples.

The human economy is adjusted to live in air at a pressure of about 760 mm. of mercury containing 21% of oxygen: a compromise of the conflict between having a blood of a tolerable viscosity for the heart to pump round the body and one which will carry an adequate amount of oxygen from the lungs to the tissues has been found at a concentration of about 5,000,000 red corpuscles per cu. mm.; and the respiratory centre is adjusted to respond to a pressure of carbon dioxide which corresponds to about 40 mm. of mercury in the alveolar air. If man goes to an altitude of 15,000 ft. above sea level, where the barometric pressure is only some 440 mm. of mercury and the oxygen pressure correspondingly reduced, he is at once in difficulties in respect of the supply of oxygen, especially if the need for it is increased by activity. No clear injury is inflicted on the tissues of the body which can be recognised by anatomical changes, but the shortage of oxygen causes plain symptoms and initiates a response the effect of which is to correct the deficiency wholly or in part. This is done by altering the sensitivity of the respiratory centre so that it responds to a lower pressure of carbon dioxide and so increasing the amount of air breathed, by changing the composition of the blood so that the haemoglobin will take up more than the normal amount of oxygen at a given oxygen pressure and by stimulating the bone marrow to grow and produce more red corpuscles so that the concentration of haemoglobin in the blood and hence its oxygen-carrying power are increased. The connecting links between the deficiency of oxygen and this complex reaction (*i.e.*, the immediate stimuli to which the reactions are responses) are not known. The result is that man can soon live comfortably under conditions so different from those to which he is accustomed that they would cause serious harm if not compensated.

*Simple wounds*.—A simple incised wound of the skin and superficial tissues made by a knife which is chemically and bacteriologically clean inflicts an uncomplicated mechanical injury on a limited number of cells in the epidermis and dermis. This is followed after a few hours by a familiar reaction: the injured part feels full and uncomfortable and is swollen, red and painful. These are the outward signs of an inflammatory reaction, which consists intimately in a dilatation of the blood vessels, an increased flow of blood to the neighbourhood and an alteration in the walls of the capillary vessels which enables liquid plasma and leucocytes to pass through from the blood to the tissue spaces. The cells killed by the injury undergo autolysis and in the course of a few days they are replaced by fresh cells derived from the adjacent epithelial cells of the skin and from the connective tissue of the dermis, as is appropriate.

The result in the end is that the wound is healed and the part restored to normal. It is impossible to suppose that this reaction is started by the absence of the cells which were originally destroyed: the actual stimulus is no doubt provided by the soluble products of their autolysis, which can be shown outside the body to have a stimulating action on cell-growth and by suitable experiments to alter the permeability of capillary vessels. The process is self-regulated and the inflammatory reaction is accessory to the restorative growth. By increasing the local circulation it raises the temperature of the part and so promotes all cellular activities; it provides plasma, which helps to wash away the soluble remains of the dead cells, and leucocytes, which eat the more resistant remnants of the cells; the discomfort which attends the hyperaemia and swelling is of value in securing rest to the injured part and freedom from further mechanical disturbance, conditions which help cell-growth and healing. The process is also automatically regulated quantitatively for the amount of autolysate, *i.e.*, the amount of stimulus, depends on the extent of the original injury. Its effect varies with the responsiveness of different tissues and, allowing for that, is determined by its concentration. If this is very high, which occurs in the ordinary way only with exceptionally massive destruction of tissue, it injures and kills cells and is responsible for the fatal condition known as secondary shock which may follow extensive injuries. Lower concentrations stimulate growth, as often happens with cellular poisons. And if the products of autolysis are present only in concentrations below the threshold value for stimulation, they have no action on the tissues. Hence in the example under consideration the response is limited to the immediate neighbourhood of the injury and the growth of cells takes place where it is needed and not in all the parts of the body to which traces of autolysate are carried in the blood. The local reaction to a bullet or a piece of glass buried in the tissues illustrates the same regulative reaction. The response consists in a growth of the connective tissue next to the foreign body without any obvious destruction of cells, due to the irritants nowhere reaching an actually poisonous concentration owing to their small solubility in the tissue fluids.

*Abscesses*.—The history of an abscess illustrates a similar kind of injury stimulus and response, complicated by the fact that the infliction of the injury is itself a process rather than an event. Abscesses can be produced experimentally by unorganised irritants, but in the natural course they are caused by bacteria which are capable of

multiplication and produce poisonous substances which are effective agents in killing and injuring cells, and as stimuli have, in a general way and apart from special actions, the same effect as the products of autolysis. At first the organisms are present only in small numbers and do relatively little damage, but as they increase in numbers the amount and concentration of their poisons increase in parallel until a substantial piece of tissue is destroyed. This undergoes autolysis and the stimulus of the autolysate is added to that of the bacterial toxins.

Hence in a developed abscess three zones may be distinguished. In the centre, where the stimuli are at their highest concentration, there is an area filled with a more or less fluid mass (*pus*) composed of leucocytes and plasma from the inflamed blood vessels in the neighbourhood, the causative bacteria and the dead cells of the part and their disorganised remains. Different tissues are killed at different concentrations; highly differentiated cells such as those of the liver, kidney and other specialised organs generally succumb easily, while the white fibrous connective tissue which forms a skeleton framework of the whole body is particularly resistant. There may therefore be an area of differential destruction at some place in the falling gradient of concentration resulting from diffusion from the central point. Surrounding the pus is a zone where the concentration of stimuli is not enough to kill cells but is adequate to stimulate them to grow; hence we find all round the pus an area of active inflammation and a wall of growing connective tissue which acts as a filter in preventing the bacteria and their poisons spreading through the body unhindered. Beyond this zone the tissues seem generally to be unaltered on superficial examination, and for the most part this is so.

That specially sensitive cells may, however, be injured is shown by the fever and feeling of illness which an abscess may cause and by the functional impairment of the secretory cells of the kidney and stomach and other delicate tissues. We also find evidence of the reception of stimuli in distant parts of the body in the growth of leucocytes in the bone-marrow. Any good-sized abscess contains in its pus more leucocytes than are present at any one time in the circulating blood, from which it follows that the formation of an abscess leads to the production of fresh leucocytes and that the cells which develop into leucocytes must be exceptionally responsive to the small amounts of stimulating substances which reach them. This deduction is confirmed by direct examination of the bone-marrow where leucocytopoiesis is found going on actively, often with a vigour which results in there being an obvious excess of these cells in the circulating blood. The purposive and reparative nature of this reaction needs no further elaboration beyond indicating that the passage of plasma out of the inflamed vessels brings antibodies (see IMMUNITY) to bear on the bacteria to which the leucocytes are also directly inimical and that the general, as contrasted with the local, rise of temperature promotes the multiplication of leucocytes at places distant from the abscess itself. The reaction does not always succeed: the bacteria may generate such a concentration of poisons throughout the body as is fatal to essential organs such as the brain and heart. On the other hand, an abscess may cure itself by destroying so much tissue that the pus finds an exit to the surface of the body and the absorption of poisons ceases because it becomes mechanically easier for them to pass outwards with the stream of plasma than inwards—a process of natural cure imitated and anticipated by surgical interference. The same result is gained if the bacteria die out or are killed off.

**Hypertrophy.**—If one kidney is removed from a young animal, the other kidney will grow in the course of a few months to twice its normal size. Similarly, if an error of development leads to one kidney being absent from the beginning, the other will be as big as two normal kidneys. In this instance the injury inflicted on the kidney is the presentation of more work to do than it was designed to discharge, and an analogous increase of both kidneys can be brought about by increasing their work by giving excess of water or of nitrogenous food. Muscle and many of the other tissues of the body show the same intimate relation between quantity of substance and quantity of function and will increase their bulk in response to greater functional requirements.

The intermediary mechanism of this *hypertrophy* has not been identified, but the similarity between the products of activity and those of autolysis is suggestive and it may well be that the normal sizes of organs which accompany normal amounts of work are determined by the soluble substances which are set free in active katabolism. So, too, if functional activity is reduced, the bulk of corresponding tissue becomes smaller. An unused muscle soon wastes, and in consonance with the quietude of old age most of the important organs shrink. If the arm is cut off at the elbow, the muscles which normally move the lower arm wither, the bones to which they are attached grow smaller, and the nerve cells in the spinal cord which actuate them may disappear.

Two points need further mention: (1) The removal of one kidney has no detectable ill-effect on an animal or man; one kidney is evidently enough to do the ordinary excretory work which is required. But the kidneys and other organs are designed to discharge, and are capable of discharging, much more than the ordinary amount of function; a muscle can at any moment do more than its average work and indeed more than it has ever been called upon to do before. The possession of this *reserve force* is an obvious teleological necessity

for survival, and so precise is the response to an increase of average work that it is maintained in hypertrophied as well as in normal organs. (2) If the increase of work is too large, hypertrophy does not occur, *i.e.*, the stimulus to hypertrophy is an amount of extra function within the range of the reserve force of the organ. This is a well recognised principle in the training of voluntary muscles for athletic or aesthetic purposes.

All these circumstances of the response to work seem to be best explained on the hypothesis that an organ is made up of a number of units, each of which requires a restorative period of rest after each of the periods of activity which are necessary for its maintenance. To fulfil the ordinary amount of function only a proportion of units is active at any one time; as their activity proceeds they become, in accordance with the general law, progressively less excitable by the stimulus which rouses their activity and eventually cease to respond. Their function is then taken over by another set of units which, after a period of rest, are more responsive. In this way a larger number of units is kept in working order than is usually required. The maximum possible work is the amount which can be achieved by all the units working simultaneously: this is the limit of the reserve force, and if it is habitually reached no units have time for the necessary rest and restoration, the organ is worn out and cannot make hypertrophic growth.

These reparative responses are not the inevitable result of the application of the appropriate stimulus: the reaction may not occur if it is unnecessary or undesirable. If the portal vein bringing blood to the left half of the liver is tied, the left lobe progressively atrophies and the right lobe hypertrophies so that at any time the total quantity of liver substance remains about normal. But if the right lobe is injured by tying its bile duct, it does not hypertrophy and the left lobe does not atrophy, though it receives blood only through the hepatic artery. The atrophy is conditioned by the total functional requirements of the body for liver tissue and does not necessarily follow the reduction in blood supply. If rabbit's blood is injected into the circulation of a normal rabbit, the excess of liquid is got rid of in a few hours, and the excess of red corpuscles in ten days or so and the normal position is regained. If such a transfusion is repeated, the excess red cells are destroyed in two or three days and the animal can be brought by practice to a habit of disposing of them promptly. If such a trained animal is bled and then transfused with an equal quantity of blood from another rabbit, no destruction of the injected blood occurs. The difference is that the extra blood is not wanted by the normal animal while the bled animal has need of it to carry oxygen: in the former it is destroyed, in the latter it is kept and used.

**Response.**—Of the circumstances which facilitate response, age and experience are the most important: their influences will often be antagonistic. The inherent capacity of a tissue to grow and discharge any of its functions steadily diminishes as the organism of which it forms a part grows older. But its available ability to do anything is influenced by whether and how often it has done it before, individually and racially. Experience in such exercises as reproducing blood which has been lost by haemorrhage or making the substances which neutralise bacterial poisons gives the same advantage as it does in the more complicated reactions of behaviour. In general, the most effective preparation for successful resistance to a large injury is the previous reception of small injuries of the same kind.

Reactions to stimuli may fail in whole or in part because the stimulus is too large and kills the whole organism or because the tissues are old or already diseased. In some instances it is the nature of the tissue which mostly determines the imperfection of the result. Blocking of one of the smaller blood vessels of the heart kills the muscle which the vessel normally supplies. The dead muscle autolyses and is removed, and its place is taken by fibrous tissue instead of by cardiac muscle, which is inherently incapable of the necessary multiplication of cells. The repair is for the time effective but it is unsatisfactory, for fibrous tissue is less elastic than muscle and is liable to tear. The nerve cells of the central nervous system never grow to repair an injury: if some of them are destroyed they cannot be replaced, and the best that can be achieved is a certain amount of functional restoration by the rearrangement and adaptation of the parts which remain. In other cases, the nature of the injury and the mode of its infliction determine the result. The common sclerosis of the kidney begins by the destruction of a proportion of the glomerulotubular units of which the organ is composed by some poison circulating in the blood. The dead tissue is cleared away and, since kidney cells cannot adequately regenerate, the gap is healed by the growth of the connective tissue. Later, which is characteristic of the disease, further destruction takes place and so on from time to time, each loss of secreting tissue being followed by fibrous tissue repair. The other units, as might be expected, hypertrophy, and up to a point function is adequately maintained, partly by the local reaction and

partly by a general rise of arterial blood pressure backed by a hypertrophied heart which tends to compensate the diminution of vasomotor mobility and control resulting from the anatomical changes. But if successive injuries continue, the limits of the possible hypertrophy of the remaining healthy tissue are exceeded and its growth is impeded by the firm fibrous tissue which comes to constitute a large part of the organ. Hence, in the end, function fails, as it finally must if repeated injuries are inflicted on tissues which cannot be vicariously replaced and are capable only of compensatory hypertrophy (*i.e.*, most specialised tissues) and not of indefinite regeneration (*e.g.*, connective tissue, blood corpuscles).

These examples are sufficient to illustrate the kind of topics which form the subject-matter of pathological study and the way in which they can at the moment be fruitfully approached. The reaction to injury (using the word in a wide sense) is a process which is initiated by some definite stimulus arising within or outside the body and generally promoted and extended by secondary stimuli which are produced by the body in the early stages of the response. The injury and the response may be local or general; general injuries may provoke local reactions, and local injuries may elicit responses in which many organs take part. The organism in this, as in other respects, has to be regarded as a coherent and essentially indivisible whole, and one must recognise the limitations of the point of view, fruitful enough in the past, from which a live animal appears as an assemblage of relatively independent cells or organs. The character of the response is such that it tends to correct in one way or another the anatomical defect or the functional derangement which is caused by the injury. Whatever the mechanism by which the result is attained, the reaction is purposive in appearance if not in intention, and its purpose is survival.

**BIBLIOGRAPHY.**—R. T. Hewlett, *Pathology, General and Special* (1923). (A. E. Bo.)

**PATIALA, SIR BHUPINDAR SINGH**, MAHARAJA OF (1891–), head of the Sikh community in India, was born Oct. 12 1891, the son of Maharaja Sir Rajendra Singh, who died in Nov. 1900. He was carefully trained, and on receiving full ruling powers at the close of 1910 maintained and greatly developed the progressive policy of the council of regency, applying himself with great assiduity to the moral and material welfare of his people. In the World War the contribution of Patiala to the Indian Army, including Imperial service troops, was increased from about 4,000 men to 28,000, and as the recognised head of the Sikh race the Maharaja exercised an enormous influence in promoting recruitment from other parts of the Punjab. His subjects saw active service in nearly all the theatres of war, and won 125 battle distinctions. He also took part in the Afghan War (1919). He took a prominent part in promoting the inauguration of the chamber of princes in 1921 and represented the princes at the League of Nations Assembly at Geneva in 1925.

**PATON, JOHN BROWN** (1830–1911), British Nonconformist divine (*see* 20.930), died at Nottingham Jan. 26 1911.

**PATON, JOHN LEWIS ALEXANDER** (1863–), British educationalist, was born in Sheffield on Aug. 13 1863, the son of the Rev. J. B. Paton, D.D., afterwards principal of Nottingham Congregational Institute. Educated at Nottingham High School and Shrewsbury School, where he was head boy, he went to St. John's College, Cambridge, where he was bracketed first in the classical tripos (Part I.) and became a fellow of his college. He studied also at Halle. After a year as a master at the Leys School, Cambridge, and 10 years at Rugby, he was appointed headmaster of University College School, London, in 1898. In Sept. 1903 he was appointed high master of Manchester Grammar School and held the post till July 1924. On his retirement a fund was raised in his name to commemorate his services to the town and district, as well as to the school. Paton was a member of the consultative committee of the Board of Education from 1907 to 1915, was lecturer on education in Victoria University and president of the Teachers' Guild (1907) and of the Modern Languages Association (1911). He was a zealous advocate of the social and religious, as well as the literary sides of education.

He published in 1914 a *Life of J. B. Paton*, and his educational works include *Chapters on the Aims and Practice of Teaching* (1896);

*The Public Schools from Within* (1906); *The Higher Education of Boys in England* (1906); *Cambridge Essays on Education* (1917); *Vocation* (1919); as well as a special report for the Board of Education on *The Teaching of Classics in Prussian Elementary Schools* (1907).

**PÄTS, KONSTANTIN** (1874–), Estonian politician, was born in the Pärner district. After completing his studies in the faculty of law at Dorpat University, he became in 1901 editor of the *Teataja* (Newsheet), the first daily paper in the Estonian language. This journal maintained radical principles and gave much prominence to economic questions. Päts then devoted his energies to organising the Estonian citizens and secured municipal administration for Estonia from the Russians, being himself appointed assistant to the Mayor of Revel. During the revolution of 1905, when the Russian authorities gave way to panic, Päts was the real ruler of the town. He brought about a compromise with the Social Democrats and thus succeeded in protecting Revel from plunder and excess. When the Russian punitive expeditions arrived he was sentenced to death by the military court, but the sentence was later commuted by the ordinary courts to imprisonment for one year.

While the Russianising wave was passing through his country during the World War Päts effected a compromise in 1915 with the Estonian nobility in connection with a reorganisation of the mediaeval system of local autonomy, which was cancelled, however, by the Russian authorities. After the revolution of 1917 Päts became head of the national administration, and on the declaration of independence of Estonia on Feb. 24 1918 he formed the first temporary Government. Owing to resistance to the plans for the formation of a Baltic Duchy he was imprisoned by the German Occupation authorities, but on the collapse of German rule he returned to the head of the temporary Government. He then began the political organisation of the peasant movement and fostered the steady growth of the Agrarian party. Päts became President of the Riikikogu and Prime Minister in 1920–2 and again in 1923.

**PATTERSON, JOSEPH MEDILL** (1879–), American publisher and editor, was born in Chicago, Ill., Jan. 6 1879. He graduated from Yale University in 1901 and joined the staff of the *Chicago Tribune*. He was elected a member of the Illinois House of Representatives in 1903, and acted as Commissioner of Public Works, Chicago, 1905–6. In 1914 he became associated with his cousin, Robert Rutherford McCormick (*q.v.*), as co-editor and publisher of the *Chicago Tribune*, which, under their direction, rose to be one of the most influential and successful papers in the United States. He acted as war correspondent in Belgium and France, 1914–5; served with the U.S. Field Artillery in Texas, 1916; and also with the A.E.F. in France, taking part in the second battle of the Marne, St. Mihiel and the Argonne. Enlisting as a private he rose to the rank of captain in the 149th F.A., 42nd Division. He was the author of *A Little Brother of the Rich* (1908); *Rebellion* (1911) and *Note Book of a Neutral* (1915).

**PATTI, ADELINA JUAÑA MARIA** (1843–1919), British singer (*see* 20.937), died at Craig-y-Nos Castle, S. Wales, Sept. 27 1919.

**PAUL, SAINT:** *see* CHRISTIANITY.

**PAUL-BONCOUR, JOSEPH** (1873–), French politician, was born at St. Aignan, Aug. 4 1873. After a brilliant university career, he joined the Paris Bar. His book *Le fédéralisme économique*, published in 1900, showed him an ardent advocate of the trade union movement, and in 1906 he was elected to the Chamber as an independent Socialist, a follower of Painlevé, by his native district of Loire-et-Cher. In 1911 M. Paul-Boncour was appointed Labour Minister in the Radical Monis-Bertaux Cabinet and in this capacity was successful in applying the new Old Age Pension Law. In the elections of May 1914, however, he was defeated by a narrow margin of 35 votes. On the outbreak of the World War he became a commander on the Lorraine front. Meanwhile, he had definitely joined the Socialist party, thus fulfilling a promise made to Jaurès, a few months before the latter's tragic end. He was returned to the Chamber at the Nov. 1919 election and at once joined forces with Léon Blum in the struggle against the national Bloc. He was again returned

in 1924, this time as deputy for Jaurès' former constituency of the Tarn. He was also one of the French delegates to the fifth and sixth assemblies of the League of Nations, 1924 and 1925, and acquired great prestige at Geneva. He became the recognised leader of the right wing of the French Socialist party.

**PAUPERISM:** see POOR LAW.

**PAVLOV, IVAN PETROVICH** (1849– ), Russian physiologist, was born Sept. 14 (old style) 1849 in the district of Ryazan in Russia, son of the village priest. He studied science at the University and then medicine at the military medical academy of St. Petersburg (Leningrad). He graduated as a doctor in 1883, and in 1884 was appointed *privat-dozent* in physiology, but he went for two years to Germany to work under Ludwig and Heidenheim. In 1890 Pavlov was appointed director of the physiological department of the institute of experimental medicine at St. Petersburg and in 1897 professor at the medical academy. In 1907 he was elected member of the Russian academy of sciences. He is famous for his leading work on the problems of digestion, *The Work of the Digestive Glands* (Eng. tr., 1902) (for which he was awarded in 1904 the Nobel Prize) and for research on cerebral activity and the theory of reflexes. His first achievements were on the physiology of blood circulation. He devised special methods of treating animals, which enabled him to make observations under normal conditions of the organism. His first papers appeared in 1878–9. From 1892–7 a series of papers on the physiology of digestion was published in the *Archives des Sciences Biologiques*. In 1897 a collected account was published in German and French, *Die Arbeit der Verdauungsdriisen*. Most of his and his pupils' researches are published in Russian. In 1907 Pavlov was elected a foreign member of the Royal Society and in 1915 he was awarded the Copley medal. See M. Dontcheff-Dezeuze, *L'Image et les Reflexes Conditionnels dans les travaux de Pavlov* (1914).

**PAVLOVA, ANNA** (1885– ), Russian dancer, was born in St. Petersburg (Leningrad) Jan. 31 1885. At the age of 10 she entered the Imperial Ballet School, attached to the Marianski Theatre, St. Petersburg, and subsequently became prima ballerina of this theatre. She later appeared at the Imperial Opera House in St. Petersburg, and in 1910 made her first visit to England. Assisted by Michael Mordkin she appeared with conspicuous success at the Palace Theatre, London, in "Le Cygne," "Les Papillons" and "Valse Caprice." In the same year she appeared in Paris with Diaghilev's Russian ballet in "Les Sylphides," "Pavillon d'Armide" and "La Nuit Egyptienne"; and also in New York in the ballet "Coppelia." Later, after making regular appearances in London for some years at the Palace Theatre, she toured in the United States. In the autumn of 1923, 1924 and 1925 she appeared with her own company at the Covent Garden Opera House, London, in "Dionysus," "Don Quixote," "Amarilla," "The Fairy Doll" and other ballets. During her career Mme. Pavlova toured all over the world, and her performances were invariably assured of an especially appreciative and enthusiastic reception in London and New York.

**PEACE CONFERENCE:** see PARIS, CONFERENCE OF.

**PEARCE, CHARLES SPRAGUE** (1851–1914), American painter (see 21.24), died in Paris, France, May 18 1914.

**PEARL, RAYMOND** (1879– ), American biologist, was born at Farmington, N.H., June 3 1879. He graduated from Dartmouth College (A.B., 1899) and the University of Michigan (Ph.D., 1902), afterwards proceeding to the University of Leipzig, the Naples zoological station and University College, London. After being instructor in zoology at the University of Michigan and the University of Pennsylvania (1902–7), he was appointed biologist and head of the department of biology at the Maine Agricultural Experimental Station in 1907. He became professor of biometry and vital statistics in the school of hygiene and public health, Johns Hopkins University, in 1918; and professor of biology in the medical school there in 1923. In 1925 he was appointed director of the Institute of Biological Research, a new division of Johns Hopkins University. He became known through his biological researches on variation in organisms, and

his studies in heredity. He was a member of the executive committee, chairman of the agricultural committee and member of the executive board of the National Research Council, 1916–9, being also chief of the statistical division of the U.S. Food Administration, 1917–9. (See DEATH.)

Pearl wrote, among other works, *Variation and Differentiation in Ceratophyllum* (with O. M. Pepper and F. J. Hagle, 1907); *Variation and Correlation in the Crayfish* (with A. B. Clawson, 1907); *Diseases of Poultry: Their Etiology, Diagnosis, Treatment and Prevention* (with F. M. Surface and M. R. Curtis, 1915); *Modes of Research in Genetics* (1915); *The Nation's Food* (1920); *The Biology of Death* (1922); *Introduction to Medical Biometry and Statistics* (1923); *Studies in Human Biology* (1924); and *The Biology of Population Growth* (1925).

**PEARSE, PATRICK HENRY** (1879–1916), Irish leader, was born in Dublin Nov. 10 1879. Educated at the Christian Brothers Schools and the Royal University of Ireland, he became editor of the *Claidheamh Soluis*, the weekly organ of the Gaelic League. He was secretary to the publication committee of the League and an energetic member of its executive. After touring Belgium to study bilingual methods, he published several *Fiana*, tales from Irish manuscripts. Pearse's chief interest was education and he approved Mr. Birrell's Irish Education Bill (see 14.788), as it gave the Irish control over their own education. He founded a school at Cullenswood, Dublin, moving it in 1910 to the Hermitage, Rathfarnham, where he continued to run it until his death. After a tour in America, Pearse joined the Irish Volunteer Movement and was commander-in-chief of the Irish forces in the rebellion of 1916. On April 30 1916 he sent out an order to his troops to surrender. He himself was arrested and executed on May 3 1916.

**PEARSON, SIR CYRIL ARTHUR** (1866–1921), British newspaper proprietor, was born at Wookey, near Wells, Feb. 24 1866, and was educated at Winchester. He early founded the business of C. Arthur Pearson, Ltd., newspaper proprietors and publishers; and after making large profits with *Pearson's Weekly* and other periodicals he founded in 1900 *The Daily Express*, a halfpenny rival to *The Daily Mail*. In 1904 he purchased *The Standard* with *The Evening Standard* (see 19.560). Under his control *The Standard* reverted to the policy of colonial preference which it had advocated nearly 50 years previously. He was a strong supporter of Mr. Chamberlain's tariff reform movement, and was vice-president of the Tariff Reform League and vice-chairman of the Tariff Commission of 1903. In 1905 he amalgamated *The Evening Standard* with *The St. James's Gazette* which he had bought a few months previously. In 1910 increasing—later complete—failure of sight obliged him to retire from the active direction of newspapers. Henceforth he devoted himself and his fortune with whole-hearted industry to efforts to ameliorate the condition of the blind. During the World War he established at his house, St. Dunstan's, in Regent's Park, London, a hospital for blinded soldiers, and became chairman of the Blinded Soldiers' and Sailors' Care Committee (1914). He also became president of the National Institution for the Blind. He was created a baronet in 1916 and G.B.E. in 1917. Sir Arthur died in London Dec. 9 1921.

**PEARSON, KARL** (1857– ), British mathematician, was born in London and educated at University College School and at King's College, Cambridge. He was called to the bar in 1882, and afterwards devoted himself to the science of eugenics, becoming a leading authority on the subject. He was subsequently appointed Galton professor of eugenics at London University and director of the Francis Galton laboratory for national eugenics. He was awarded the Darwin Medal of the Royal Society, of which he was elected fellow in 1896, for his numerous contributions to the mathematical theory of evolution and heredity. Professor Pearson was the editor of *Biometrika* from 1902–24, and his other publications include *The Ethics of Free-thought* (1887, 1901); *The Chances of Death, and other Studies in Evolution* (1897); *Grammar of Science* (1899, 1900, 1911); *National Life from the Standpoint of Science* (1901); *Tables for Statisticians* (1914); *The Life, Letters and Labours of Francis Galton* (1925).

**PEARY, ROBERT EDWIN** (1856–1920), American Arctic explorer (*see* 21.30) died in Washington, D.C., Feb. 20 1920. On account of his discovery of the North Pole (1909) he was promoted rear-admiral in 1911 and received by special Act the thanks of Congress. The same year he was U.S. delegate to the International Polar Commission in Rome. During his later years he was much interested in aerial navigation. He was the author of *The North Pole* (1910) and *Secrets of Polar Travel* (1917).

**PEAT** (*see* 21.31), the fibrous substance formed chiefly of the remains of bog mosses growing in swampy places, has long been used for fuel, firelighters, fertilisers and litter for animals and in the production of gas, charcoal and various by-products. In the present century its use in making bandages, wadding, spinning-fibres, paper, cardboard, millboard, non-conducting coverings, building blocks, finger plates and other moulded articles has formed the subject-matter of numerous patents. More than half the water of fresh peat is so closely associated with its organic constituents that it is practically impossible to reduce by pressure the water content to an amount, e.g., 25%, desirable for most commercial purposes.

*Methods of Treatment.*—Ekenberg's wet-carbonising process has been improved in details. In this process, a mixture of peat and water circulates through an arrangement of highly heated tubes; by this treatment the cell structures of the peat are broken down and the liberated water is then removed by pressure. In Messrs. Testrup, Rigby and Söderlund's process (British patent specification No. 17610 of 1911), apparatus for wet-carbonising and briquetting peat is worked in association with a generator plant adapted for the recovery of ammonia. The process may be worked so that, by using some of the peat briquettes in the generator, the heat requirements of the process are met and ammonia and a surplus of gas and briquettes are obtained. In the process of Dr. Perkin and the Bettisfield Trust Co. Ltd. (British specification No. 288993), the peat is macerated and transferred to a digester, which delivers it into a large cooling chamber in which the pressure on the peat is reduced suddenly; the peat is then pressed, cooled and briquetted. The briquettes are hard, contain about 18% of water and are said to yield a high quality charcoal. Other processes for facilitating the removal of water from peat, by pressure, are the repeated cutting and mixing of the peat until it is a pasty mass, like mustard (Herman de Meijer); grinding to a very fine state in ball or tube mills (Nielsen); treating with slaked lime and removing the released water by means of centrifugal machines or presses (Sirocco Engineering Co., Belfast); and mixing with about one-third of dried peat (Brune-Horst process), coke dust and other substances.

Many successful processes for treating peat on a large scale are modifications of the old air-drying process. At the Alfred Peat Bog, Ontario, the excavated peat is transferred to the drying ground, cut into blocks and exposed to the air by mechanical means and stored under cover. The peat at the Wiesmoor Peat Station, Germany, is macerated before being spread on the drying ground. Near Vislanda, Sweden, where the Ekenlund system has been used, the peat is spread on the drying ground by an arrangement of travelling screens; the peat blocks obtained are crushed, dried and pulverised to obtain a very dry peat powder for use in locomotives. At Juurkopi in Finland and Schwanberg in Oldenburg the peat is cut into and washed into storage pits by jets of high-pressure water. This process is useful in working bogs containing trunks of trees.

It has been proposed to obtain charcoal, oils, wax, ammonium sulphate and acetic acid by low temperature carbonisation of peat. Dry peat has been used in gas generators at Portadown, Ireland. The Fuel Research Board also has obtained good results by using peat in Glover-West vertical retorts. The Power-Gas Corporation Ltd., making use of Mond generators at Orenzano in Italy, in Westphalia, at Osnabrück in Hanover and near Moscow, has employed "wet peat" (60 to 70% water) for obtaining gas, charcoal and by-products. (*See also FUEL PROBLEMS.*)

(T. E. L.)

**PEEL, ARTHUR WELLESLEY PEEL, 1ST VISCOUNT** (1829–1912), British statesman (*see* 21.39), died at Sandy, Beds., Oct. 24 1912.

He was succeeded by his son William Robert Wellesley Peel (b. 1867) who, in 1916, was chairman of the committee on the detention of neutral vessels. In 1919 he was appointed Under-Secretary for War, in 1921 became Chancellor of the Duchy of Lancaster, and from 1922–4 was Secretary of State for India. When Mr. Baldwin formed his second Government in Nov. 1924 he was made First Commissioner of Works.

**PEKING** (*see* 21.61), the capital of the Chinese republic, with a population estimated at 1,181,400 in 1923, has been much improved since the revolution of 1911. The duties of the municipality are carried out by the Ministry of the Interior, which aims at making Peking a model city. A Chinese self-government association was formed in 1921, to agitate for the foundation of a municipal council. The chief streets have been metalled and lighted; water, sewage and electric light systems installed; new roads made and tramways laid; and a municipal fire brigade, a central hospital, a model prison and a Government industrial museum (with a factory for native handicrafts) opened. There are a number of foreign banks, and the Chinese banks have made great progress in recent years; the Peking Bankers' Association, founded in 1919, opened a fine building in 1920. A wireless telephone system to Tientsin was started in 1922. The reorganised police have recently been replaced by the military.

The Kalgan railway had reached Paotow in 1923, but the road-bed was not completed. Railway traffic conditions have been improved by the location of the termini of the lines to Mukden and Hankow at the reconstructed Chien Men, the great south gateway of the Tartar city. A circular line to link up the stations, which has involved the destruction of the curtains of most of the gateways, has been built; the wall of the Imperial City has been pierced in a number of places, and broad thoroughfares driven through the Forbidden City. The deposed Manchu Emperor keeps his court in a small part of it, less than half a mile square. The three palaces have been repaired, and the Temple of Heaven is open to the public; roads have been made in the lovely park, barracks built and a library and museum of Imperial treasures opened. The national university was reorganised in 1917, and women students have been admitted since 1920. The Yenching University, in temporary premises in Peking, has acquired 175 ac. of land to the east of the city, and buildings were being erected as rapidly as possible in 1925. A medical school was opened at the Peking Union Medical College in 1919. Most of the recent institutions, the Government offices and many banks and commercial businesses are housed in buildings of Western style; these, however, are chiefly conspicuous in the vicinity of the legations, and the general features of Peking are little changed. The number of resident foreigners has increased considerably, and, although the city has not been opened to foreign trade, many business houses have been established with the tacit consent of the Chinese authorities.

The authority of the Peking Govt., though recognised by the Powers, did not in 1925 in reality extend outside the capital, and many anti-foreign disturbances, including a strike of the Chinese servants at the British legation, occurred. A tariff conference on the question of the revision of tariffs met in the city in the autumn of 1925, but was at a deadlock early in 1926, when the Peking Govt. was in desperate straits for lack of funds, trade was stagnant, and the city menaced by opposing armies and by threatened attacks by the Canton Govt. (*see* CHINA).

**PELLETAN, CHARLES CAMILLE** (1846–1915), French politician and journalist (*see* 21.69), died June 4 1915.

**PELOUX, LUIGI** (1839–1924), Italian general and politician (*see* 21.71), died in Rome Oct. 26 1924.

**PENCK, ALBRECHT** (1858– ), German geographer, was born at Reudnitz, near Leipzig, Sept. 25 1858. He studied at the University of Leipzig and afterwards taught in Munich. He was a professor in the University of Vienna from 1885 to 1906 when he went in the same capacity to Berlin. His chief work in that city was the extension of the marine museum and the geographical institute of the university, of which he became director.

Penck travelled extensively in various countries for the purpose of study and collected much valuable scientific material. His researches were particularly devoted to climatic phenomena of ancient and modern times. He made special studies in connection with the Ice Age and the formation of glaciers in the Tertiary and Diluvial periods, and also some outstanding contributions to scientific knowledge in the sphere of hydrography. Before the World War he acted for a time as professor at Columbia University, New York City. In the field of practical geography Penck did valuable work in promoting the production of a map of the earth on a scale of 1: 1,000,000 (see MAP).

His publications include *Die Vergleichen der deutschen Alpen* (1882); *Die Donau* (1891); *Morphologie der Erdoberfläche*, 2 vol. (1894); *Die Alpen im Eiszeitalter*, with E. Brückner, 3 vol. (1901-9). He also edited the *Geographische Abhandlungen*, the *Bibliothek geographische Handbücher* and the *Bibliothek Länderkundlicher*.

**PENLEY, WILLIAM SYDNEY** (1852-1912), British actor (see 21.99), died at St. Leonards-on-Sea Nov. 11 1912.

**PENNSYLVANIA** (see 21.105), a state of the United States of America. The population in 1920 was 8,720,017, an increase of 1,054,906 over 1910. The rate of increase, 13.8%, was considerably lower than that of the preceding decade, 21.6%. The estimated population in 1925 was 9,317,647. In 1920 the population of the cities of over 50,000 inhabitants was:—

|                        |           |                      |         |
|------------------------|-----------|----------------------|---------|
| Philadelphia . . . . . | 1,823,779 | Pittsburgh . . . . . | 588,343 |
| Scranton . . . . .     | 137,783   | Reading . . . . .    | 107,784 |
| Erie . . . . .         | 93,372    | Harrisburg . . . . . | 75,917  |
| Wilkes-Barre . . . . . | 73,833    | Allentown . . . . .  | 75,502  |
| Johnstown . . . . .    | 67,327    | Altoona . . . . .    | 60,331  |
| Chester . . . . .      | 58,030    | Lancaster . . . . .  | 53,150  |
| Bethlehem . . . . .    | 50,358    |                      |         |

*Agriculture.*—The production of chief crops (in thousands of bushels) is shown in the following table:—

|                     | 1923   | 1919   | 1909   |
|---------------------|--------|--------|--------|
| Wheat . . . . .     | 24,381 | 23,454 | 21,564 |
| Maize . . . . .     | 58,912 | 61,450 | 41,494 |
| Oats . . . . .      | 33,793 | 29,183 | 28,173 |
| Buckwheat . . . . . | 4,449  | 4,756  | 4,797  |
| Rye . . . . .       | 3,583  | 3,208  | 3,497  |

The production of potatoes in 1923 was 23,406,045 bu.; of apples, 11,735,320 bu.; of peaches, 1,953,700 bu.; of pears, 636,515 bushels.

*Mineral Production.*—The production of coal in recent years (in thousands of net tons of 2,000 lb.) was as follows:—

|                      | 1924 <sup>1</sup> | 1923    | Average 1916-20 | Average 1911-5 |
|----------------------|-------------------|---------|-----------------|----------------|
| Anthracite . . . . . | 90,214            | 93,339  | 92,741          | 9,233          |
| Bituminous . . . . . | 123,530           | 171,880 | 168,532         | 157,229        |

<sup>1</sup> Estimated.

The production of coke (in net tons of 2,000 lb.) was 25,625,000 in 1923; 13,992,000 in 1922; 23,638,000 in 1920; 25,632,000 in 1915.

*Manufactures.*—In 1914 Pennsylvania became the foremost State in the value of silk production, displacing New Jersey. Her 1914 production was valued at more than one-third of the national total, and the State had more than two-fifths of all the employees in the industry. In hosiery manufacture Pennsylvania in the same year produced 39.7% of the national quantity and 41.2% of the national value. The iron and steel and kindred industries in the period 1909-23 more than doubled the value of their output, that of steel works and rolling-mills rising from \$500,344,000 in 1909 to \$1,292,222,273 in 1923, while the output of blast furnaces increased in value from \$168,578,000 in 1909 to \$377,227,181 in 1923. In the manufacture of tin plate, Pennsylvania in 1914 had 13 establishments with 2,368 employees and an output valued at \$36,795,990. In 1919, with eight establishments only, the number of employees had increased to 12,311 and the value of the product was \$115,642,300. In 1923, in all manufacturing industries combined there were in the State 19,055 establishments, with an average number of wage-earners of 1,995,066 and a total output valued at \$7,438,609,142.

The following table shows the figures for the more important industries in 1923, as compared with 1921:—

|                                                        | Years        | Establishments | Wages                        | Value of products              |
|--------------------------------------------------------|--------------|----------------|------------------------------|--------------------------------|
| Steel Works and rolling-mills                          | 1923<br>1921 | 186<br>190     | \$272,189,711<br>146,957,133 | \$1,292,222,273<br>645,759,871 |
| Blast furnaces                                         | 1923<br>1921 | 53<br>42       | 20,468,325<br>11,766,246     | 377,227,181<br>164,558,350     |
| Foundry and machine shops (general)                    | 1923<br>1921 | 1,017<br>1,092 | 94,135,554<br>62,121,550     | 344,064,225<br>238,197,741     |

*Education.*—Two progressive steps a decade apart mark the development of the public schools. The first was the adoption of the school code of May 18 1911; the second, the enactment of what is known as the Finegan programme (named after the State superintendent of public instruction) by the legislature of 1921. The school code of 1911 was virtually a codification of all the laws governing the public school system and a general unification, with many new features, of administration measures. Its important sections provided for independent control of taxation and borrowing by school boards, with minimum and maximum tax rates varying according to the size of the school district; reduction of the number of members in school boards so as to simplify official business; establishment of a state board of education; establishment of a state school fund, and general provisions for the better selection of text-books and for the development of higher education.

The measures of 1921 (the Finegan programme) raised the standard of qualification of teachers and county superintendents; established a uniform salary schedule for teachers; increased the State aid to schools; made appropriations for normal schools so that they might be supported without tuition fees; centralised the State school administrative system by the creation of a State council of education; standardised the elementary courses in public and private schools; and required that teaching be in the English language and from texts in English.

The following table shows the number of pupils and teachers employed in the years ending July 1920-3:—

| Year              | Number of pupils enrolled in public schools | Number of teachers |
|-------------------|---------------------------------------------|--------------------|
| 1919-20 . . . . . | 1,592,591                                   | 44,862             |
| 1920-1 . . . . .  | 1,624,915                                   | 45,485             |
| 1921-2 . . . . .  | 1,709,477                                   | 48,000             |
| 1922-3 . . . . .  | 1,840,766                                   | 49,843             |

The total expenditure, state and local, for education increased from \$52,544,036 in the school year 1913-4 to \$175,000,000 in

1923-4. In 1924 the State appropriation for education reached \$21,000,000, the largest in the history of the State, being an increase of \$6,000,000 over that of the preceding year.

*Finance.*—The revenues of the State more than doubled from 1909 to the end of 1920. The receipts in 1909 were \$28,945,210; in 1920 \$62,071,293. This does not include \$11,800,000 derived in 1920 from the sale of State road bonds, a fund kept separate from the regular state moneys. The Treasury disbursements in the fiscal year 1920 were \$74,960,112, \$18,000,000 higher than 1919, the increase being due to road construction. For the year ending May 31 1924 the receipts were \$103,123,948 and the expenditure during the same period rose to \$97,157,571. On June 30 1924 the total number of commercial and savings banks was 1,650, with total resources or liabilities of \$5,526,654,000; capital, surplus and undivided profits of \$924,673,000; and deposits of \$3,924,883,000. Of these banks, the national banks numbered 864, with total resources or liabilities of \$2,756,792,000; capital, surplus and undivided profits of \$411,427,000 and deposits of \$1,826,986,000.

*History.*—The first two constitutional amendments of the period 1910-25, adopted in 1911 and 1913 respectively, had to do with the courts—the amendment of 1911 increasing the number in Philadelphia Co. and merging those in Allegheny Co.; the amendment of 1913 altering the judicial and municipal terms to conform with an amendment of 1909, which changed the date of the elections from Feb. to November. Another amendment of 1913 enabled municipalities, except Philadelphia, to embark upon the construction or acquisition of waterworks, subways, etc., even though their cost brought the indebtedness above the limit allowed; it also permitted arrangements whereby the interest and sinking-fund charges were paid from the principal until the properties should have been completed and in operation for one year. A limit of 10% of the assessed valuation of taxable property in a municipality was fixed for such indebtedness, three-fifths of the electors of the municipality having first to give their assent to the increase.

On Nov. 2 1915 the people voted on four proposed amendments and adopted three of them. The first and most important prepared the way for workmen's compensation. The second enabled Philadelphia to increase its borrowing capacity under conditions similar to those set forth in the amendment of 1913. The third enabled the general assembly to enact laws providing a system of registering, transferring, insuring and guaranteeing land titles by the State or the counties. Amendments passed by the legislature in 1915 and 1917 were approved by the voters in 1918, one enabling the State to issue bonds to the amount of \$50,000,000 for the improvement of highways, and the other enlarging Philadelphia's borrowing capacity by removing the previous restrictions which confined its increased indebtedness to the construction or acquisition of waterworks, subways, etc. An amendment approved at the general election in 1920 enabled the assembly to levy "graded or progressive taxes." The result of these numerous amendments was manifest in the session of 1919, when a bill was passed authorising the Governor to appoint a commission to study the constitution with a view to general revision or to amendment by sections.

The number of boards, commissions, etc., functioning under the State Government was greatly increased between 1919 and 1925. The Legislature in 1911 created a Bureau of professional Education under the State department of public instruction, its purpose being to regulate the education of physicians, dentists and pharmacists. A Bureau of medical education and licensure, under the department of public instruction, was also created by Act of 1911 to examine into conditions in the medical schools and conduct the examination of students applying for State licences. Another important change of 1911 was the reorganisation by legislative enactment of the State highway dept. and the undertaking of an extensive system of highways to be built and maintained entirely from State funds.

In 1913 the Department of Labour and Industry was created, with power to enforce the "laws relating to the safety, health, and prosperity of employees and the industries." A workmen's

compensation board was set up, the State was divided into districts, and the administration of compensation was carried on through referees and members of the board. A state workmen's insurance board was created the same year for the purpose of administering the insurance fund provided in the Workmen's Compensation Act. The Legislature, in 1913, also did away with the old State railway commission, substituting a public service commission with much greater powers.

The year 1915 saw the reorganisation of the department of agriculture with the creation of a commission on agriculture to appoint all officers and employees of the department and prepare the budgets of the department and the state livestock sanitary board. Other new boards of that year were the one on vocational training under the department of public instruction; the board of censors on all motion pictures; the prison labour commission, to supervise the manufacturing industries of inmates of penal institutions; and the veterinary medical examining board. The bureau of municipalities under the Department of Labour and Industry was a development of 1917, intended to classify and make available statistics and other information tending to improve the government of municipalities. In the same year five new boards were created; the State military board, which has the power to grant pensions not exceeding \$12 per month to widows or minor children of national guardsmen killed on active duty; the board of pharmacy; the board of optometrical education, examination of licensure; the board of commissioners on uniform state laws and the public school employees' retirement board.

The Legislature of 1917 also created a commission on public safety and defence, for which was appropriated \$2,000,000. It functioned during the two years of American participation in the World War, but was succeeded in 1919 by the commission on public welfare, which received an appropriation of \$500,000 to carry on the work of reconstruction and of collecting records of the State's part in the World War. In 1919 a bureau of statistics and information was created under the State department of internal affairs, the bureau of municipalities was transferred from the department of labour and industry to the department of internal affairs, and a bureau of rehabilitation was created under the department of labour and industry.

The year 1919 witnessed the adoption of two Federal amendments; the prohibition amendment of Feb. 25 and the Woman Suffrage amendment on June 24. The Legislature in 1921 created a welfare department, which assumed the duties of the former board of public charities, the lunacy committee, the prison labour board and connected activities. In 1923 a new administrative code was enacted, providing for the consolidation of the existing administrative agencies of the State into 12 departments, viz.: State and finance, justice, public instruction, military affairs, agriculture, forests and waters, labour and industry, health, highways, welfare property and supplies, and commerce.

Governors of the state between 1911 and 1925 were John K. Tener (Rep.), 1911-5; Martin G. Brumbaugh (Rep.), 1915-9; William K. Sproul (Rep.), 1919-23; Gifford Pinchot (Rep.), 1923-.

(A. E. McK.)

**PENNSYLVANIA, UNIVERSITY OF** (see 21.114).—The period from 1910 to 1926 marked some of the greatest developments of this university in 185 years. The standards of admission to all schools were raised, and the number of students was definitely limited in most of the schools. The law, medical and graduate schools now require academic degrees for admission, and the dental school at least two years of academic training. In 1925 the engineering schools adopted a new system of admission, requiring two years of academic training; and subsequently required two years of intensive study in engineering subjects for the technical degree. Admission to all other undergraduate schools has been restricted almost entirely to applicants who have graduated from the upper half of a standard four-year approved high school, and no students are admitted on condition. The courses in veterinary medicine and dentistry have been increased to four years.

*New Developments.*—During this period the following schools and departments have been added to the university. In 1910

the Henry Phipps Institute was transferred to the university. In 1912 the original college department was divided into the Towne scientific school, the Wharton school of finance and commerce and the college; and the dental school was merged with the Thomas W. Evans Museum and Dental Institute. In 1914 a school of education was founded and schoolmen's week established. In 1916 the medico-surgical college and hospital were merged with the university. In 1917 the department of military science was established. In 1918 the Philadelphia Polyclinic and College for Graduates in Medicine were merged with the university. In 1919 the graduate school of medicine was founded. In 1920 the laboratory of hygiene was organised as a school of hygiene and public health; and the school of fine arts, including architecture and music, was established. In 1921 a department of dental hygiene was instituted, and in 1923 the Moore School of Electrical Engineering. Dr. Josiah H. Penniman was acting provost from 1921 to 1923, when the position of president was created and Dr. Penniman became both president and provost, which positions he was occupying in 1926.

For the sessions of 1925-6 there were in the University of Pennsylvania 17,509 students; of these, 4,215 were women. The students were distributed as follows: college, including arts and science, biology and college courses for teachers, 2,815; summer school, 2,230; Towne scientific school, including mechanical, civil and chemical engineering, 166; Moore school of electrical and engineering, 93; fine arts, including schools of architecture, music, 442; Wharton school, 2,677; various extension schools, 4,597; school of education, 1,508; graduate school, 1,393; school of medicine, 472; hygiene, 2; graduate medicine, 130; law school, 342; dental school, 542; dental hygiene, 42; veterinary school, 58.

During 1910-25 many new buildings were added to the campus, among them several dormitory houses, including one for women students; a new surgical pavilion and other additions to the hospital groups; the Duhring Stack and the Henry C. Lea wing were added to the library, and several wings to the university museum; Bennett Hall; the school of education and the graduate school; zoological building; the Evans dental institute; and a university stadium seating eighty thousand persons. Ground was also broken for a new gymnasium, an anatomical laboratory building, Irvine Hall, auditorium building, etc. The university plant, with these new structures, will consist of 110 ac. and approximately 75 buildings.

The treasurer's report of June 30 1924 shows the total assets of the university to be about \$33,000,000, including grounds, buildings and endowment. The buildings, grounds and university plant are valued at about \$18,000,000. Not included in these figures are several plants affiliated with the university such as the Evans Dental Institute, the Wistar Institute of Anatomy, etc., the values of which are more than \$3,000,000. There are also 130 fraternities, of which 93 operate houses, and of these 60 own property valued at more than \$3,000,000. The total annual receipts in 1925 were approximately \$4,000,000. The sum of \$1,803,560 was spent on educational salaries and \$919,477 on other salaries. On May 1 1925 there was organised the "University of Pennsylvania Fund," the object of which is to secure at least \$45,650,000 before the 200th anniversary of the university in 1940; more than \$5,500,000 had been subscribed by 1926. (E. F. Sm.)

**PENSIONS.**—In most civilised countries a considerable portion of the working population can look forward to pensions in their old age, while Great Britain and her Dominions, the United States and other countries provide pensions for those who were disabled during the World War. Pensions are also given to officers and men who have served in the army, navy or air force. Further, Germany, Great Britain and other countries have state schemes for providing old-age pensions, and in addition many business firms have pension schemes.

### I. GREAT BRITAIN

Great Britain has an elaborate national scheme which provides pensions for all who attain the age of 70, and also for widows, blind persons and certain others who are under that

age. These form part of the national system of social insurance and are described in this work in that connection (*see INSURANCE, SOCIAL*). Pensions are given to civil servants, these being calculated at so much for each year of service up to a maximum of half the salary. In addition, a lump sum, equal to a year or more of salary, is paid on retirement. Municipal authorities, banks and many business firms have pension schemes for their employees. These vary very much in character, but most of them are contributory, the employee paying a certain percentage, perhaps 2½%, of his annual salary and the firm contributing a like amount. Great Britain has also civil list pensions, as they are called. The Government provides £1,200 each year, which is spent in giving pensions to literary men and their dependants, and others whose circumstances are impaired.

**War Pensions.**—The World War made necessary a vast expenditure on pensions, and in Great Britain a large organisation was set up to control this. The Ministry of Pensions came into existence in Dec. 1916, but it did not take over the administration for pensions for long service, which still remain under the War Office, the Admiralty or the Air Ministry. Its headquarters are at 2 Sanctuary Buildings, 18 Great Smith Street, Westminster, London, S.W. 1, and under it are five regional districts. Much of the work is done through local committees. The amount of work carried on by the Ministry just after the conclusion of the War was so enormous that at one time it employed 32,000 persons. As, however, claims were settled and the pensioners began to die off, the amount was reduced. In 1924-5 its expenditure, mainly on pensions, was £66,947,000.

**Pension Rates.**—Pensions are granted to all those who have been disabled, wholly or partially in the War, and to their dependants; also to the dependants of those who were killed. A disablement pension is usually first granted on a temporary basis for 12 months, afterwards being made final when the disablement is sufficiently stable. Such pensions are reckoned on a percentage basis—a total disablement being taken as 100%. The lowest figure entitling to a pension for disablement is 20%. Thus, if a disablement is assessed at 50%, the man would receive 50% of the full rate of pension and his wife and children, if eligible, 50% of the allowances. Disablement assessed at less than 20% is compensated for by a gratuity or an allowance for a stated number of weeks. A grant of this kind, however, must not exceed a maximum of £200.

The rates of pensions in force in 1926 are as follows: For 100% disablement a private receives 40s. a week and his wife 10s. 7/6 is paid for the first child and 6/3 for each other child. A widow over 40 receives 26s. 8d. and a widow under 40 20s. a week. From the beginning of the War to March 31 1925 the total number of pensions paid to officers and their relatives was as follows:—

|                  |        |
|------------------|--------|
| Officers         | 59,787 |
| Widows           | 11,616 |
| Children         | 12,844 |
| Other dependants | 8,028  |
| Nurses           | 2,415  |

The number of pensions paid to non-commissioned officers and men and their relatives to the same date was as follows:—

|                    |           |
|--------------------|-----------|
| Men                | 1,269,706 |
| Children           | 1,015,271 |
| Widows             | 248,367   |
| Children of widows | 399,349   |
| Other dependants   | 410,988   |

On March 31 1925 the number of persons in receipt of pensions was as follows:—

|                        |         |
|------------------------|---------|
| Officers               | 25,500  |
| Widows of officers     | 9,100   |
| Children of officers   | 8,500   |
| Dependants of officers | 6,400   |
| Nurses                 | 1,100   |
| Men                    | 472,000 |
| Widows of men          | 148,000 |
| Dependants of men      | 346,000 |
| Motherless children    | 18,000  |

The estimated cost of pensions and their administration during the financial year 1925-6 was £63,504,900. (A. W. H.\*)

## II. THE UNITED STATES

*Pensions Prior to the World War.*—During the period 1910-26 various amendments and additions to the U.S. War pension laws were made by Congress, including provision in 1915 for a double pension in case of death or disability resulting from an aviation accident. The most recent amendment was contained in an Act, approved May 5 1926, increasing the pensions of those who have lost limbs or been totally disabled or become totally blind in the military or naval service of the United States.

The following table shows the number of pensioners on the roll and the total disbursements for pensions during the period 1910-25:—

| Fiscal year | Soldiers on roll | Widows on roll | Total disbursements for pensions |
|-------------|------------------|----------------|----------------------------------|
| 1910        | 602,180          | 318,903        | \$159,974,056.08                 |
| 1920        | 285,110          | 299,363        | 213,295,314.00                   |
| 1921        | 267,713          | 290,955        | 258,715,842.54                   |
| 1922        | 256,828          | 282,965        | 253,807,583.37                   |
| 1923        | 253,605          | 278,700        | 263,012,500.00                   |
| 1924        | 248,049          | 270,194        | 229,994,777.00                   |
| 1925        | 244,657          | 260,382        | 217,150,602.00                   |

A detailed specification of the pensioners on the roll, June 30 1925 was as follows: Civil War—soldiers, 126,566; widows, etc., 241,193; nurses, 60; War with Spain—soldiers, 101,702; widows, etc., 18,363; nurses, 169; Regular Army—soldiers, 12,399; widows, etc., 3,762; Indian Wars—soldiers, 3,924; widows, 3,034; War with Mexico—soldiers, 17; widows, 1,257; World War—soldiers, 49; widows, etc., 21; War of 1812—widows, 21.

*World War Compensation.*—The first provision for pensions arising out of casualties of the World War was made by Act of Congress, Oct. 6 1917, which provided for compensation for death or disability arising from personal injury suffered or disease contracted of all persons in service, including women in the army and navy nursing corps in line of duty in the War. The death compensation varied with the relationship of the recipient and the number of dependants. Compensation for disability depended upon its seriousness and duration. The Act also provided that in addition an injured person should be furnished such medical and hospital service and medical supplies and appliances as should be reasonably necessary and, in cases of permanent disability, courses of rehabilitation, re-education and vocational training. Provision was also made for allowances to families and dependants of all enlisted men and insurance at peace-time rates to any person, man or woman, in active military or naval service. The administration of the various parts of the Act was committed to three organisations: the Bureau of War Risk Insurance, the United States Public Health Service and the Federal Board for Vocational Education. By Act of Congress, Aug. 9 1921, all the World War Veteran's relief activities were consolidated in the United States Veteran's Bureau, and this resulted in great economy in administration and a correspondingly greater efficiency. By Act of Congress, June 7 1924, the "World War Veterans Act, 1924," a consolidation and revision of the previous legislation was accomplished, and under this statute with minor amendments, the U.S. provision for World War pensions or "compensation," insurance and other forms of assistance to World War Veterans and their dependants has been administered.

Up to June 30 1925 1,001,931 compensation claims had been filed, 490,258 of which were allowed, 497,103 disallowed and 14,570 were pending. At that date compensation payments were being made on 277,935 claims and the total disbursements for death and disability compensation had amounted to \$730,107,737.29.

**PENSIONS, MINISTRY OF.**—This department of the British Govt. was set up by Act of Parliament in Dec. 1916, to deal with pensions arising out of services during the World War. The Act transferred to a minister, responsible to Parliament, the powers and duties of the Admiralty, the War Office and the Chelsea

Commissioners, "in respect of the payment of pensions and grants to officers and men, to their widows, children and dependents and to persons in the nursing services of the naval and military forces." The administration of pensions for services in the army, navy and air force was left with the departments responsible for the general administration. The work of the ministry grew enormously during the War period, and just afterwards. In 1921 it had a staff of 26,000 persons, and at the end of 1920 it was paying pensions to over 1,800,000 men, women and children, the total number of persons benefiting being estimated at nearly 3,500,000. The medical work of the ministry was on a correspondingly large scale. It had many hospitals and a large staff of medical men, who at one time examined over 20,000 cases each week. The supply and repair of artificial limbs was an important branch of the work.

After the War the work of the ministry was decentralised and in 1919 and 1920 11 regions were established, although the number was afterwards reduced to seven. These seven are London, Birmingham, Manchester, Bristol, Newcastle-upon-Tyne, Edinburgh and Cardiff. Each is governed by a director, assisted by a commissioner of medical services and others, who carry on—(1) Medical examinations; (2) Awards of pensions; (3) Control of hospitals; (4) Supervision of local pension committees. The headquarters of the ministry are at 2, Sanctuary Buildings, Great Smith Street, London, S.W.1. and in 1923-4 it disbursed in salaries and expenses over £73,000,000.

**PÉREZ GALDÓS, BENITO** (1845-1920), Spanish novelist (see 21.139), died at Madrid Jan. 4 1920.

**PERIODICALS** (see 21.151).—This article deals with the new reviews which have appeared since 1912 treating of language, literature, politics, art, fiction and topic subjects. For the most part only those periodicals which are still being issued are recorded and the year of their first appearance is given.

Naturally the economic strain of the World War caused the collapse of many publications which might have survived in more prosperous times. Even apart from wars the appearance and speedy disappearance of new reviews is a common event of the publishing world, and has been no less common in the last dozen years. An example of a periodical which was killed by the War is *Blast* (1914). *To-day*, a literary review, ran from 1917 to 1923, *Life and Letters* appeared in 1923 and 1924 only, while the *Anglo-French Review*, which began in 1919, had an equally short career.

## I. THE BRITISH EMPIRE

*The Appeal to Popular Tastes.*—The period is remarkable for the growth of new periodicals appealing to the popular taste rather than for its more solid and learned reviews. To give lists at all approaching completeness of this class of publication would be impossible within the space allotted to this article. A few examples will be given taken from such subjects as the cinema, wireless, motoring, dancing, popular fiction, domestic economy, etc. Among periodicals concerned with the cinema stage are the *Ciné-Musician* (1925); *Cinema Pie* (1919); *Cine-shows* (1919); *Cinema Chat* (1919-20), continued as *Home News* (1920). Reviews treating of the recent developments of wireless telegraphy are *The Radio Review* (1919); *The Broadcaster and Wireless Retailer* (1922); *The Wireless Magazine* (1925); *The Wireless Constructor* (1924); *Brighter Wireless* (1925). In the automobile world in addition to a large number of trade and advertising journals there are many reviews intended for the amateur, such as the *Autocycle* (1913) and the *Motor Owner* (1919). The popularity of dancing is responsible for *Dancing Life* (1921); *Dance-land* (1922); *Dancing Annual* (1923) among others.

*Fiction and Domestic Economy.*—The magazines devoted entirely to popular fiction are possibly more numerous than those of any other class. Among them are *The Premier Magazine* (1914); *Home Mirror* (1919) *Short Stories* (1920); *Gaiety* (1921); *Choice Story Magazine* (1923), *True Love-Story Magazine* (1924); *Merry Magazine* (1924); *Standard Stories* (1925). The contrast between the gay appearance of these periodicals and the sobriety of the fiction magazines of the 19th century is striking. These

magazines are to a great extent taking the place of the earlier monthly miscellanies, the family magazines. The popular periodical of the 19th century was largely devoted to fiction, but also contained a certain amount of instructive matter; its tone was eminently serious. The present-day popular journal, on the other hand, is devoted entirely to light fiction, has frankly no other object than that of amusement, nor is there any attempt to convey moral instruction under the guise of fiction. The change may be in part accounted for by the existence of a wider reading public, embracing less educated classes.

Equally striking is the change which has taken place in the form of the periodicals concerned with domestic economy and the life of women, of which the best examples are *Good House-keeping* (1922) and *Woman* (1924) and *Woman's Pictorial*. These journals have been influenced by the American woman's magazine *Vogue*, which appears to circulate throughout the English-speaking world. They have a distinctly artistic standard and are not content with the mere fashion-plate. They are remarkable also for the advantage which they take of modern developments in colour printing. The increased attention paid to advertising has enabled these and similar magazines to be more lavish in the manner of their production, while the advertisers or advertising agents have themselves devoted especial care to matters of typography and the lay-out of the printed matter. This is reflected also in magazines intended for children, a class of periodical which has much increased its numbers. The *Merry-Go-Round* (Oxford, 1923) is the best example of a well printed children's magazine. Others are *Toby and Wonderful Playthings* (1921), *My Magazine* (1914), which developed from *The Children's Encyclopaedia*, and *The Children's Companion* (1923).

*Literature*.—Turning to the more serious periodicals we find that the general review, a publication dealing with politics, literature and the arts, etc., is less frequent than the more specialised review. The majority of the new journals are definitely political, literary or artistic. Dealing with English literature and language we have *The Review of English Studies* (1925) and *The London Mercury* (1919), of which the first treats mainly of earlier English literature, while the second is chiefly devoted to contemporary literary criticisms. *The Poetry Review* (1909) is concerned with the criticism of poetry and also contains original verse. Of literary reviews which publish original fiction and verse there are *The Adelphi* (1923); *The Bermondsey Book* (1923); *The Calendar of Modern Letters* (1925); *The New Criterion* (1926), originally founded as *The Criterion* (1922); *The New Coterie* (1925). One well-known literary review, the *Athenaeum* (1828), has joined forces since 1921 with the *Nation* (1890), and thus become one of those literary weeklies which must be classed as newspapers. Of this class there has been one new journal of note, *The New Statesman* (1913), which appears to have become well-established. On the whole the weekly review of politics and literature is losing ground between the more specialised monthlies and quarterlies on the one hand and the Sunday newspapers on the other hand. Such papers as *The Observer* (1791), and *The Sunday Times* (1904), besides being definitely newspapers, are to all intents and purposes general weekly reviews.

*Politics*.—Of periodicals which are mainly political there are *The New Europe* (1916–20); *The Round Table*, a quarterly review of the politics of the British Commonwealth (1910); *The Conservative Review* (1925); *The Labour Monthly* (1921); *The Polish Review* (1917), and *Twentieth-century Russia and Anglo-Russian Review* (1915), both discontinued; *The Balkan Review*, now *Eastern Europe* (1919); *The Anglo-Italian Review* (1918), now discontinued; *Africa and Orient Review* (1920); *The Commonwealth*, a monthly magazine of enlightenment and progress (1925). Here may be recorded *The League of Nations Official Journal* (1922). Of periodicals devoted to the arts there are *Apollo*, a journal of the arts (1925); *The Arts Gazette* (1919); *Art-work* (1924), *Colour* (1914), an art journal which is remarkable for its reproduction in colour.

*Theology, Education, etc.*—Theological journals are *Theology*, a monthly journal of historic Christianity (1920); *The Venture*, a monthly journal of Christian thought (1915; new series,

1919–21) and *The Pilgrim*, a review of Christian politics and religion (1920). Educational journals are *Education for the New Era*, continued as *The New Era* (1920); *The Torchbearer*, a review of education (Birmingham, 1924). Other specialised reviews are *The Cambridge Historical Journal* (1923) and the *Psychic Research Quarterly* (1920), now *Psyche* (1921).

*Typography*.—Throughout the period here considered there has been a continued advance in the standard of typography and book production in periodical literature, as well as in the book proper. Several reviews devote space to purely typographical criticism, while in their form many of them show a great improvement on their predecessors of the last century. Most countries have their periodicals devoted to the study of typography, some of which are mentioned below. In England *The Imprint* (1913) survived less than one year. It was followed in 1923 by *The Fleuron*, a journal of a very high standard devoted entirely to the art of printing. Several advertising journals connected with the trades of printing and publishing are noteworthy for their form, e.g., *The Linotype Record*, *The Monotype Recorder*, magazines issued by typefounding companies, and the *The Bookmark* (1925), and *Now and Then*, a periodical of books, periodicals issued by the publishing houses of Dent and Jonathan Cape respectively.

*University Publications*.—Almost all these journals are published in London, where the book trade tends to be centred more and more. In England almost the only exceptions are a few periodicals issued in connection with, if not by, the universities. Such are for example two reviews dealing with modern languages, *The French Quarterly* (Manchester, 1919) and *The Bulletin of Spanish Studies* (Liverpool, 1923).

*Scotland*.—In Scotland there are two new general, mainly literary, reviews, *The Northern Review* (Edinburgh, 1924) and *The Scots Magazine* (Glasgow, 1924).

*Ireland*.—In Ireland, since the formation of the Free State, there has been considerable activity in periodical publications. Already, in 1912, we had *Studies*, an Irish quarterly review of letters, philosophy and the sciences. We now have *The Dublin Magazine* (1923), a general non-political periodical. A popular magazine entitled *Banba* lasted for two years only, 1921 and 1922. *An Branar*, also, a journal written in Irish, which began in 1919, has been discontinued.

*Overseas Dominions and India*.—In this section there is but little new work to record. Canada has a number of popular magazines which show the influence of the United States. *The Canadian Forum*, a monthly journal of literature and public affairs (Toronto, 1920) is the chief review of a more ambitious class. *Art in Australia*, a quarterly magazine, published at Sydney, appears to have come to an end in 1923. South Africa has two new reviews, *The Cape*, an independent review of South African life and politics (Cape Town, 1915), and *The South African Quarterly* (Johannesburg, 1919); *The Eastern Illustrated Review*, a quarterly (1918) and *The Malayan Chronicle* (1923) are both published at Singapore. At Calcutta is published *Rupam*, an illustrated quarterly journal of oriental art (1920). Of other Indian journals issued in English *The Hindu Review* (Calcutta, 1913–4) and *The New Review* (Bombay, 1917–9) both had a short existence.

## II. OTHER COUNTRIES

*United States*.—The number of periodicals published to-day in the United States is certainly much larger than in any other country, and especially in the class of popular magazines. All that has been written above about these journals in England applies with much greater force to the United States; indeed in the style and scope of these magazines England is mainly an imitator. If the art of advertising has changed the appearance of journals in this country, its effect has been still more pronounced in America. No lists need here be given. Almost equally numerous are the technical and scientific periodicals, which cannot be dealt with here.

Of new reviews in our restricted sense there are two of particular importance, *The American Mercury* (New York, 1924), a

monthly review, mainly literary, and *Foreign Affairs* (New York, 1922), a political journal. Other literary reviews are *The Modern Review* (Boston, 1922), a quarterly; *The Unpopular Review* (1914) now discontinued; *Poetry*, a magazine of verse (Chicago, 1912), containing besides original verse some criticism; a journal entitled 1924, which began in July of that year. Another political journal concerned with European affairs is *The Adriatic Review* (Boston, 1918). Art magazines are *The Print Connoisseur* (New York, 1920), a quarterly, and *Art in America* (New York, 1918). Of journals concerned with philology, *The Romantic Review* (New York, 1910), a quarterly, and the *International Journal of American Linguistics* (New York, 1917), devoted to the study of the language of the American Indians, are of importance. Other specialised reviews are the *Hispanic American Historical Review* (Baltimore, 1918-22); the *Anglican Theological Review* (New York, 1918); *The Psychoanalytical Review* (New York, 1914); the *American Journal of Physical Anthropology* (Washington, 1918). Naturally the great majority of specialised journals are issued by learned societies and are therefore outside our scope; it should be remembered, however, that such publications are extremely numerous in the United States, a country which is showing a Teutonic industry in research, with the advantage of more abundant financial support.

Finally it follows from the fact that a second revival of printing has taken place in America, that a host of journals connected with the printing trade have been issued, including one first class review concerned with typographical history, *Ars Typographica*, which took on a new and enlarged form with its second volume in 1925.

*France*.—The position of Paris as the literary centre of France and perhaps the most important literary centre in the world is reflected in the publication of new periodicals. Of reviews devoted to literary criticism and history we have the *Chronique des lettres françaises* (1923); *La Connaissance*, revue des lettres (1920); *Les Nouvelles littéraires* (1922); *Les Feuilles libres* (1918); *Revue de littérature comparée* (1920); *Etudes italiennes* (1919); and *La Nouvelle Revue française* (1919). Of more general reviews, dealing with political affairs as well as literary, we have *Europe* (1923); *L'Esprit nouveau*, revue internationale illustrée (1920); *Les Lettres* (1919); *La Minerve française* (1919); *Le Navire d'Argent* (1925); *La Revue belge* (1918); *La Revue anglo-américaine* (1923); *La Revue du siècle* (1925); *La Revue européenne* (1923); *La Revue universelle* (1920); *Transatlantic Review* (1924). Reviews dealing mainly with serious fiction are *Commerce* (1924); *Demain* (1924); and *Action*. *Cahiers, individualistes de philosophie et d'art* (1920). The chief new political reviews are *Annuaire du monde musulman* (1923); *Le Monde libre* (1919); *La Nation Tchèque* (1915); *La Voix de l'Arménie* (1918). Of periodicals dealing with the arts, there are *Arethuse*, revue d'art et d'archéologie (1923); *Beaux Arts* (1923); *L'Art vivant*, revue bi-mensuelle des amateurs et des artistes (1925); *Revue des arts asiatiques* (1924); *Revue d'art oriental* (1920); *L'Acropole*, revue du monde hellénique (1925), a classical journal. Historical reviews are *Archives de la grande guerre* (1919) and the *Revue des Etudes Napoléoniennes* (1912). Finally we record two periodicals which treat especially of book production and typography, *Byblis*, miroir des arts du livre et de l'estampe (1921) and *Le Livre et l'Estante* (1923). All these are issued at Paris. The *Revue du Lyonnais* (Lyons, 1921), is an important review published in the provinces.

*Germany*.—For the large number of periodicals, mainly illustrated and popular, issued in Germany during the World War, the reader is referred to the bibliographies of War literature. The majority of the serious and important German reviews have survived the War and the critical years following. As to the new publications they appear to have suffered, if not in number, at any rate in form, many of those here recorded being but slender publications. New general reviews, mainly literary, are *Die Hilfe* (Berlin, 1914); *Freie Deutsche Bühne* (1919), now *Das blaue Heft* (Berlin, 1921); *Die neue Schaubühne* (Dresden, 1919); *Die neue Bücherschau* (Munich, 1919); *Der Piperbote* (Munich,

1924); *Europäische Revue* (Leipzig, 1925); *Neue deutsche Beiträge* (Munich, 1922); *Deutsche Vierteljahrschrift für Literaturwissenschaft* (Halle, 1923); *Der neue Merkur* (Munich, 1917); *Vers und Prosa* (Berlin, 1924). More political are *Der Jude* (Berlin, 1916); *Neue Ukraine* (Berlin, 1923, published in Russian); *Ost. Europa*, zeitschrift für Gesamtfragen des europäischen Ostens (Königsberg, 1925). Reviews of art are *Das Kunstblatt* (Potsdam, 1917); *Faust* (Berlin, 1921); *Kunst und Antiquariat*, Zeitschrift für Kunst und Bücherfreunde (Munich, 1925). Two reviews deal with oriental art, *Ostasiatische Zeitschrift* (Berlin, 1912) and *Artibus Asiae* (Dresden, 1925). Treating of classical antiquity there are *Gnomon* (Berlin, 1925) and *Die Antike* (1925). More specialised periodicals are the *Zeitschrift für slavische Philologie* (Leipzig, 1924); *Zeitschrift für Individualpsychologie* (Munich, 1914); *Volk und Rasse* (Munich, 1926), an ethnological journal. Even before 1912 Germany had a number of reviews devoted to the history of printing and typography; to these have been added *Monatshefte für Bücherfreunde und Graphik-sammler* (Leipzig, 1925); and *Die Bücherstube* (Munich, 1920).

*Italy*.—The new Italian reviews are *Bilychnis*, rivista di studi religiosi (Rome, 1913); *Nuovi Studi medievali* (Bologna, 1923); *Rivista Indo-Greco-Italica di filologia, lingua, antichità* (Naples, 1917); *Archivum Romanicum*, nuova rivista di filologia romana (1917), and *Il Nuovo Giornal Dantesco* (1917), both published at Florence; *Dedalo*, rassegna d'arta (1920); *Il Convegno*, a literary review started since the War; *Aegyphus* (1920), an archaeological journal; *Musica d'oggi* (1922), all published at Milan. This growth of periodical literature in the chief industrial town of Italy is significant.

*Spain*.—The most important of the few new reviews of note is *Hermes* (1917), a literary periodical published at Bilbao. Madrid has had two new literary reviews, *Cervantes* (1916) continued as *Cervantes*, *Revista hispano-americana* (1918-20, but no longer published), and the *Revista de Occidente* (1923).

*Belgium*.—*Congo* (1920) is a political review, *La Revue belge* (1924), a general political and literary magazine. There is also *Buzavtion*, revue internationale des études byzantines (1924), and a bibliographical curiosity of the War, *La libre Belgique* (1915), secretly produced during the German occupation. All these are published at Brussels.

*Holland*.—*De Kronik* (Hague, 1914); *De Stem* (Arnheim, 1920), an annual; *Het Getij* (Amsterdam, 1915); *Kakatoe* (Amsterdam, 1915) and the *Haagsche Maanblad* (Hague, 1924), are mainly literary reviews. *Maanblad voor beeldende Kunsten* (Amsterdam, 1924), is an art journal. *Het Boek* (1912), formerly the *Tijdschrift voor Boekwezen*, now published at the Hague, is practically a new periodical, and is one of the chief continental journals concerned with the history of printing. *English Studies* (Amsterdam, 1919) is also worthy of mention.

*Scandinavian Countries*.—*Det nya Sverige* (Stockholm, 1918), *Den Nye Literatur* (Copenhagen, 1919), and *Edda*, *Nordisk tidsskrift för litteraturforskning* (Oslo, 1914), are all literary reviews. *Holberg Aarbog* (Copenhagen and Oslo, 1920), is an annual concerned with the dramatist Holberg. The *Nordisk Tidsskrift för Bok-och Biblioteks-väsen* (Stockholm, 1914), is an important review devoted to typographical matters.

*Switzerland*.—*La Revue de Genève* (1920) is a general, political and literary journal.

**BIBLIOGRAPHY**.—The value of indexes as a guide to the mass of important material which is often to be found only in the pages of periodicals has long been recognised. Well-established periodicals meet this want by issuing their own indexes and by reviewing whatever has appeared on their subject in other periodicals. A good review on any particular subject is itself the best guide to the current literature of the subject. In addition to this, two classes of publications embrace the bibliography of reviews: first, lists of periodicals and secondly subject-indexes. Of lists in 1925 appeared *The World List of Scientific Periodicals*, which records more than 20,000 current scientific and technical journals. A second volume is to follow, which will be a guide to the libraries containing these journals. *The Times* has published the *Tercentenary Handlist of English and Welsh Newspapers, Magazines and Reviews, 1620-1920*. The fourth edition of *Severance's Guide to the Current Periodicals and Serials of the U.S.A.* and *Canada* appeared in 1920. *Willing's Press Guide*, *The Writers' and Artists' Year-Book*, the *Literary Year Book* and other similar

annuals contain lists of periodicals written in English. *The American Newspaper Annual* is a comprehensive work for the United States. France has an *Annuaire des journaux, revues et publications périodiques*. Germany has produced two comprehensive subject indexes, the *Bibliographie der deutschen Zeitschriften-Literatur* and the *Bibliographie der Fremdsprachigen Zeitschriften-Literatur*, the second of which appears to have come to an end in 1915. *The Athenaeum Subject-Index*, now *The Subject Index to Periodicals*, published by the London Library Association is the most important index produced in England. *The Readers' Guide to Periodical Literature*, now *The International Index*, is an American publication. Faxon's *Annual Magazine Subject-Index*, a subject-index to a selected list of American and English periodicals, is issued at Boston. In the *New Guide to Reference Books*, published by the "American Library Association" (Chicago, 1923), there is a valuable chapter on the bibliography of periodicals. Finally in Italy the "Biblioteca della Camera dei Deputati" has issued a *Catalogo metodico degli scritti contenuti nelle pubblicazioni periodiche italiane e straniere*, a useful index for certain subjects, but extending only to 1914. (See also NEWSPAPERS.) (A. F. J.)

**PERISCOPE**, an optical instrument used in land warfare and in submarine navigation to enable an observer to see his surroundings while remaining under cover or submerged. It invariably includes among its optical elements two mirrors or reflecting prisms to change the direction in which the light travels, the first to divert it down the interior of a tube which normally forms the frame of the instrument, and the second to guide it into a direction convenient for observation. In addition there is usually a more or less complex telescopic system, and in some types devices are added for taking ranges, for measuring the speeds with which objects are moving, or for searching the whole sky, to which may be added means for varying the magnifying power of the telescope. Some of these devices are necessarily complex.

The simplest type of periscope, consisting of a tube and two mirrors at its ends placed parallel to one another and at an angle of  $45^\circ$  with the axis of the tube, is not of recent origin, but the great developments which have been made in modern times are due to requirements for submarine navigation. These developments secure a large angular field of view when the tube is of considerable length and yet of restricted diameter and give an enlarged image. As in other military instruments, clear vision through the periscope even under adverse conditions is of great importance, and the beam of light brought to the observer's eye must therefore be of a diameter large enough to fill his pupil when it is somewhat widely opened. These various conditions tend to be opposed to one another, so that the design of each instrument represents a compromise which may vary over a considerable range as more or less importance is attached to one or other of these requirements.

A typical submarine periscope consists externally of a tube about 30 ft. long and 6 in. in diameter except for a length of from two to three feet at the top, where the diameter may be reduced to two inches or even less. At the lower end a length of several feet of the full diameter is required for passing through the long stuffing box where the instrument enters the hull of the submarine. A diameter of about six inches is needed to resist the bending movements caused by the resistance of the water as the submarine advances; an increase in the diameter adds to the resistance offered by the periscope to the boat's progress. The narrowing at the top is introduced to make the part which projects above the surface of the water less conspicuous. The optical effects of this constricted portion are so pronounced that the dimensions assigned to this part determine the design of the instrument. It is debatable whether the tendency has not been to attach too much importance to this reduction in the diameter of the tube.

If an observer looks through a series of tubes of the same diameter but of different lengths, placing his eye close to the end of the tube, his field of view will be smaller with a long tube than with a short one. The factor governing the extent of the field of vision is obviously the proximity of his eye to the front end of the tube. Thus in a periscope the only way of increasing the field of view is to locate the eye virtually near the top of the tube by inserting therein a system of lenses which, in addition to satisfying other conditions, will form an image of the observer's eye in

the required position. These further conditions ensure the transmission to the real eye of all the light (assuming for the moment that all losses of light on refraction through the lenses of the instrument may be neglected) that reaches the virtual eye position: roughly, they involve the insertion in the tube of a lens at intervals proportional to the distance of the virtual eye from the open end of the tube. Thus if the field of view is to be doubled the number of lenses needed in a tube of given length and diameter must be doubled. Consider now two tubes, the length and diameter of one being twice that of the other. If they are both used to accommodate optical systems giving the same field of view, the distance of the virtual eye position from the open end will be twice as great with the large tube as with the smaller, and this will be secured with the same number of lenses in each instrument. But another factor enters which modifies this result: i.e., fills the observer's pupil with light, the larger instrument will fill with light a pupil of twice this diameter. The transmission down the large tube of beams of this width will be useless, and since diameter of beam and angular field are reciprocally proportional, the angular field may be doubled in the large tube for a fixed number of lenses without reducing the illumination below that obtained with the smaller tube.

Another way of stating this result is that for a given angular field and a given diameter of emergent beam the number of lenses required is proportional to the length of the tube and inversely proportional to the square of its diameter. As an illustration, the number of lenses required to transmit a given beam down a tube three feet long and two inches in diameter will transmit the same beam down a tube 27 feet long if the diameter is increased to six inches.

The chief objection to an increase in the number of lenses in an instrument is the reduction in the brightness and clearness of the image it involves. The brightness suffers because the amount of light transmitted through the instrument is decreased owing to reflection, absorption and scattering; the clearness is diminished because, of the transmitted light, a decreasing proportion is concerned with the formation of the real image, the rest forming spurious images or appearing as mere fog. When these additional lenses belong to a narrow part of the instrument, their powers, being inversely proportional to the interval between successive lenses—that is, proportional to the inverse square of the diameter of the tube—are high, and their effects in introducing irremovable aberrations, such as chromatic aberration and curvature of field, are correspondingly great. From the optical point of view that narrowness in the tube, even for a short length, is very detrimental to the production of a good instrument.

The optical system in a periscope is intended to give a view roughly similar to that obtained by direct vision, and is thus telescopic; that is to say, it has an infinitely great focal length, and exhibits objects with a constant angular magnification. Objects viewed through a tube present an illusive appearance of being less than their natural size, and to compensate for this it is usual to provide an angular magnification of one and a half times as the equivalent of a naked eye view. With this magnification an angular field of about  $40^\circ$  is ordinarily attained, with an emergent beam of diameter 4 or 5 millimetres.

The use of a simple telescope in addition to the top and bottom reflectors would not allow such a field of view to be attained in a periscope of normal length. The typical method of developing more complex telescopes to meet the conditions consists in adding one telescope to another, the combination being itself of course necessarily telescopic. If two telescopes of the astronomical type are combined, pointing—in the astronomical sense—in the same direction, a large magnifying power results and the illumination is feeble. If, however, they are pointed in opposite directions, with their objectives facing one another, the resulting magnifying power will be the ratio of the magnifying powers of the component telescopes, and therefore may be kept down to the low value desired, while at the same time the leading lenses, which constitute the eyepiece of the first telescope, will be of the small diameter needed for the leading portion of the system. A

system of this kind will yield satisfactory images near the axis whatever the separation of the two objectives may be; but in the outer parts of the field, owing to the obliquity of the corresponding beams between these lenses, the brightness of the image is reduced as the separation is increased. The brightness accepted in the outer parts of the field is considerably less than that at the centre, but it may not be reduced beyond the point at which the change—which is gradual from the centre outwards—becomes obvious to the observer. There is thus a limit to the length attainable by the use of two telescopes, but the addition of more telescopes gives correspondingly greater lengths.

In many periscopes a higher power than one and a half, nearly always six, can be introduced instantly in place of the lower power without any change in the focus or displacement of the centre of the field of view. In order to avoid loss of light or reduction of the field as seen by the observer (the "apparent" field), the change of power must be effected at the top of the instrument, that is in the narrow portion of the tube. This requirement of course adds to the difficulties inseparable from a narrow tube. Of the many different means of changing the power employed by different makers only one will be illustrated.

When it is required to search the complete sky, the top reflector must consist of a prism, or alternatively of two prisms

Fig. 1.

placed with their reflecting bases close together and parallel to one another. The way in which light from different altitudes is directed down the tube is evident from fig. 1.

#### PRINCIPLES OF CONSTRUCTION

The accompanying series of illustrations (figs. 2 to 4) show the general principles of construction, together with the appearance

of the two ends, in one of the many patterns of submarine periscope that are made by Messrs. Barr and Stroud. Fig. 2 shows diagrammatically the arrangement of the optical parts in a bifocal periscope giving a field of view of  $40^\circ$  with a power of  $1\frac{1}{2}$  and a field of  $10^\circ$  with a power of  $6\frac{1}{2}$ . The system will be considered first as a high power instrument. Light enters through the plane parallel plate *a*, which is sealed into the tube, making a watertight joint; immediately afterwards it is reflected downwards by the prism *b*, and is then refracted in turn by the lenses *e*, *f* and *g*, which constitute an inverted astronomical telescope. Of these lenses *e* corresponds to the eye lens, *f* to the field lens of the eyepiece and *g* to the object glass. This telescope is followed by a second, comprising four lenses, *h*, *k*, *m* and *n*: *h* is the objective, *k* a collector lens, which may be moved along the axis of the tube for focusing and the remaining pair *m* and *n* together constitute the eyepiece of the periscope. The lower reflector is the prism *l*, to which the lens *m* of the eyepiece is cemented.

The first telescope produces an angular magnification measured by the ratio of the focal lengths of *e* and *g*. Since the instrument is used with the eyepiece and object in the reverse of the usual order, the image formed appears to be diminished instead of magnified, and, of course, is inverted. The second telescope magnifies this diminished image in a ratio depending on the relation of the focal length of the pair of lenses *h* and *k* to that of the eyepiece *m* and *n*. By a proper selection of these focal lengths it is evident that a power of six can be obtained without imposing any inconvenient restrictions on any of the lenses. Moreover, the inverted image formed by the first telescope is reinverted by the second, so that objects viewed through the periscope present their natural appearance. To obtain a power of one and a half with a correspondingly augmented field, Messrs. Barr and Stroud introduce a Galileian telescope in front of the system just described. Since such a telescope gives an upright image, no inversion results from the introduction of the additional lenses, and no change in the position of the real image plane of distant objects occurs if these lenses are in correct telescopic adjustment. Since a diminished angular magnification is to be obtained, the eye lens—that is, the negative lens *c* of the Galileian telescope—precedes the objective *d*. When the high power is in use the lenses *c* and *d* are swung to one side, as at *c*<sub>1</sub> and *d*<sub>1</sub>, against the side of the tube. Fig. 2 shows the paths of two beams through the low power system, that along the axis having the full cross section admitted by the lenses *g* and *h* and the other from a point at the edge of the field showing by its smaller cross section the diminution in illumination which takes place.

Fig. 3 shows the upper end of a Barr and Stroud periscope of the sky-searching type. The window is inclined to the axis of the tube to give the large angular field required. Within the window may be seen the prism by the rotation of which about a horizontal axis the direction of sight may be varied from the zenith to below the horizon according to the principle illustrated in fig. 1. The lower end of the periscope is illustrated in fig. 4. The handles are used to rotate the instrument about its axis, and so enable the line of sight to be directed to any part of the horizon as required. The bearing of any object to which the periscope is directed may be read on the scale seen in the upper part of this figure. When the instrument is not in use the handles may be folded into a vertical position out of the way. The eyepiece, surrounded by a rubber eye-guard, is seen between and slightly above the handles. In focus with the image of external objects are seen the graduations of vertical and horizontal scales. These correspond to suitable angular intervals by means of which the apparent sizes of objects may be obtained with fair accuracy, and from this an estimate of distance, for example, may be derived. Inset in the top of the field of view, so as to be visible without taking the eye from the eyepiece, is a view of a portion of the bearings scale, which is projected into the field of view by means of a small prismatic telescope.

<sup>1</sup> This page is much too short to enable a drawing to scale to be printed thereon.

In addition to reading the bearing it is important that the observer should be able to bring any object into the centre of the field of view without removing his eye from the eyepiece. This involves control over the angle of elevation of the line of sight, ability to adjust the focus and possibly the power of introducing coloured screens before the eye. In this periscope the top prism may be adjusted for elevation as required by rotating one of the handles about its axis, and the focusing adjustment and the light filters are controlled by means of the two milled heads seen projecting from the bottom of the periscope in fig. 4. The change of power is effected by rotating the second handle. All these controls are placed conveniently for the observer. The coloured glasses are placed within the tube and lie close to the eye lens.

In ordinary use the low power telescope is employed, and a change is only made to the high power when it is desired to observe an object that has been sighted more minutely than is possible with the low power. By using the low power, which embraces an angular area sixteen times as great as the high power, large regions can be observed much more rapidly than with the high power with its smaller field of view. Means are provided, but not illustrated, for raising and lowering the periscope rapidly. The recognised method of use is to break the surface for a series of rapid observations rather than keep the top above water, since the continuous trail made at the surface as the submarine travels under the water betrays her presence to an enemy.

Special provision has to be made for desiccating the air in the interior of the periscope from time to time. As material for the tubes bronze has been used on account of its non-magnetic character—a most important requirement; also nickel steel, which is only slightly magnetic. The latter material is somewhat corrodible by sea-water. Very slight action of this kind is serious, since it causes the tube to work shiftily in its watertight gland. Messrs. Barr and Stroud use immadium bronze, which they find preferable in all respects to the earlier materials.

The principles of construction of periscopes for use on land are the same as those described for naval instruments. The conditions to be satisfied are in general less stringent than in submarine periscopes, and in the absence of important special features it is unnecessary to give illustrations of these instruments. See the article "Periscope" in *Dictionary of Applied Physics*, vol. 4.

(T. Sm.)  
**PERKIN, WILLIAM HENRY** (1860– ), British chemist (see 21.173), was in 1912 appointed Waynflete professor of chemistry at Oxford. His numerous investigations on the constitution of the terpenes and of various alkaloids and natural colouring matters, which are described in a very brilliant and numerous series of papers in the *Transactions of the Chemical Society*, were carried out with great skill and originality. These investigations formed the scientific basis of the great synthetic dye industry, in the development of which Germany played the leading part.

**PERMANENT COURT OF INTERNATIONAL JUSTICE.**—The Permanent Court of International Justice was created by an international agreement concluded at Geneva, Dec. 16 1920, and consisting of a statute for the establishment of the Court and a protocol of signature by which 48 States declared their acceptance of the statute and of the jurisdiction of the Court. At the close of 1925 this protocol had been ratified by 37 of the 48 signatories, including all the principal Powers, except Germany, Russia and the United States of America. On Jan. 28 1926 the Senate of the United States, upon the formal initiative of the President, advised and consented that the United States adhere to the protocol of Dec. 16 1920, with certain reservations designed to put the United States upon an equal footing in respect of the Court with the several members of the League of Nations. Germany applied in 1926 for membership in the League of Nations, and, if admitted, it is reasonable to assume will adhere to the Court protocol.

## I. CONSTITUTION AND JURISDICTION

**Judges.**—The Court consists of 11 judges and four deputy judges, who are elected for terms of nine years and may be re-

elected. The seat of the Court is at The Hague. It holds regular annual sessions, and, unless otherwise provided by rules of the Court, the regular session begins on June 15 of each year and continues as long as may be deemed necessary to finish the cases on the list. It elects its own president and vice-president, appoints its own registrar and makes its own rules regulating procedure. The president and registrar are required to reside at the seat of the Court. If at any time the full number of 11 judges cannot be present, the deputy judges are called upon to make up the number; nine judges being necessary to make a quorum. The statute requires that the members of the Court shall be a body of independent judges elected regardless of their nationality from amongst persons of high moral character who possess the qualifications required in their respective countries for appointment to the highest judicial offices or are jurisconsults of recognised competence in international law.

Not more than one national of any State at one time may be member of the Court. The members receive regular salaries and are not permitted to exercise any political or administrative function, or to act as agent, counsel or advocate in any case of an international nature. Every member is required, before taking up his duties, to make a solemn declaration in open court that he will exercise his powers impartially and conscientiously.

**Litigants.**—Only States or members of the League of Nations can be parties to cases before the Court. The rights of a private person, therefore, can be brought before the Court only by the Government of the State or quasi-state of which he is a citizen. The Court is open unconditionally to the members of the League of Nations and also to the states mentioned in the annexe to the League Covenant, and it is open to other States upon condition of their accepting the jurisdiction of the Court and undertaking to carry out in good faith its decisions and not to resort to war against a State complying therewith. The jurisdiction of the Court comprises all cases which the parties refer to it and all matters specially provided for in treaties and conventions in force.

There was much discussion whether this jurisdiction should be made generally compulsory, so that whenever one party to any international controversy wished to bring the case into court, the other party would be bound to submit to the jurisdiction. Many States being unwilling to subject themselves to so comprehensive an obligation, the question was disposed of by including in the protocol and statute an optional clause, which the several States were at liberty to sign or refrain from signing, and under which the States signing recognised as compulsory, in relation to each other, the jurisdiction of the Court in legal disputes concerning (a) the interpretation of a treaty, (b) any question of international law, (c) the existence of any fact which, if established, would constitute a breach of an international obligation (d) the nature or extent of the reparation to be made for the breach of an international obligation. At the close of the year 1925 this optional clause had been signed by 23 States. France was the only Great Power included in this list. Since the Court began its work, its jurisdiction under the head of "matters specially provided for in treaties and conventions" has been enlarged by many new treaties and conventions providing that disputes between the parties shall be submitted to the Court.

**Procedure and Practice.**—The statute requires the Court to apply in its decisions (1) international conventions, whether general or particular, establishing rules expressly recognised by the contesting States; (2) international custom as evidence of a general practice accepted as law; (3) the general principles of law recognised by civilised nations; (4) judicial decisions and the teaching of the most highly qualified publicists of the various nations, not as binding, but as subsidiary means for the determination of rules of law.

The official languages of the Court are French and English. The hearings are public. Every decision is by a majority of the judges present at the hearing. The judgments are required to state the reasons on which the decisions are based. They are delivered in open court, and are printed and published in a regu-

lar series of reports. They are final and without appeal, but a judgment is binding only between the parties and in the particular case. Dissenting judges are entitled to deliver separate opinions.

Special chambers of five judges each are appointed by the Court for three years to hear and determine labour cases arising under Pt. XIII. of the Treaty of Versailles and cases relating to transit and communications under Pt. XII. of the Treaty of Versailles. In such cases the judges are assisted by technical assessors. With a view to the speedy dispatch of business, the Court forms annually a chamber of three judges, who, at the request of the contesting parties, may hear and determine cases by summary procedure.

Special pains are taken in the statute to ensure that in each case there shall be in the Court some judge familiar with the laws, customs and peculiarities of each country which is a party to the controversy, and if in any case there is no member of the Court coming from the country which is a party litigant, that party may name an additional judge to sit in the Court in that case. For this purpose several parties in the same interest are reckoned as one party only.

*Advisory Opinions.*—The Court has provided by rules for giving an advisory opinion upon written request from the Assembly or the Council of the League of Nations containing an exact statement of the question accompanied by all documents likely to throw light upon it. When such a request is received, the registrar is required to give notice to the members of the Court, to the members of the League of Nations, to the States mentioned in the annexe to the Covenant and to any international organisations which are likely to be able to furnish information on the question. Opinions are given only after hearing all parties concerned and after deliberation by the full Court; and the requests and opinions are printed and published in a special collection of reports.

## II. ELECTION OF JUDGES

The judges and deputy judges of the Court are elected by separate concurrent votes of the Council and the Assembly of the League of Nations, a majority vote of the members of each of those bodies being necessary to an election. The voting is confined to a list of eligible candidates nominated by the members of the old Permanent Court of Arbitration at The Hague established by the Hague Conferences of 1899 and 1907. That Court of Arbitration was made up by each Power signatory to the Hague Convention for the Pacific Settlement of International Disputes selecting not more than four persons who were required to be "of known competency in questions of international law, of the highest moral reputation and disposed to accept the duties of arbitrators." The persons thus selected were inscribed as members of the Court of Arbitration in a list which was sent to all the contracting Powers.

When a controversy was to be brought before the Court of Arbitration, five persons were to be selected from this list by the parties to constitute the tribunal to hear and determine the case. The list of members of the Court of Arbitration accordingly really constitutes a panel from which in each case the arbitral tribunal is selected, and this panel is composed of as many little national groups as there were States signing the Hague Convention and making appointments under it. Under the statute of 1920 creating the Permanent Court of International Justice, when a judge of the new court is to be elected, each of these national groups in the old court is called upon to nominate not more than four candidates, not more than two being of their own nationality. All the nominations thus made are entered in a single list to which the votes of the Council and the Assembly for the new judges are confined.

The experience of many years has shown that the character of the men appointed to the old Court of Arbitration was such as to withdraw them to a great degree from the most disturbing influences of local politics and to make them specially familiar with the persons who would be fitted for judges of the new court, and the statute conferring the power of nomination upon them

contains an express provision that "before making these nominations, each national group is recommended to consult its highest court of justice, its legal faculties and schools of law, and its national academies and national sections of international academies devoted to the study of law." The statute creating the new court also lays down for the guidance of the Assembly and Council in casting their votes the following rule: "At every election the electors shall bear in mind that not only should all the persons appointed as members of the Court possess the qualifications required, but the whole body also should represent the main forms of civilisation and the principal legal systems of the world."

If after three meetings there remains a vacancy for which no candidate shall have obtained an absolute majority of votes both in the Assembly and in the Council, then a joint conference committee is provided for, which shall endeavour to agree and report upon a candidate, and the conference committee may, by unanimous agreement, go out of the list of nominations for a candidate. If the conference fails, then the judges of the Court already elected may proceed to fill the vacancy by selection from amongst the candidates voted upon in the Assembly or in the Council.

## III. ORGANISATION AND WORKING

The first election of judges to constitute the Court was held at Geneva Sept. 14-6 1921. The list of eligible candidates proposed by the members of the old Court of Arbitration included 89 names, and from this list 11 judges and three deputy judges were elected by concurrent ballots of the Council and Assembly, and a fourth deputy judge was chosen upon the report of a conference committee accepted by both bodies. The judges elected were respectively citizens of France, Great Britain, Spain, Denmark, the Netherlands, Switzerland, Italy, Japan, Brazil, Cuba and the United States of America. The deputy judges were citizens of Norway, Rumania, the Serb-Croat-Slovene State and China. The members elected met at The Hague on Jan. 30 1922, and proceeded to organise the Court by electing Judge Loder (Holland) as President and Judge Weiss (France) as Vice-President, appointing Mr. Ake Hammarskjöld (Norway) as registrar, and adopting rules regulating the constitution and working of the Court and procedure before it.

The first session for the transaction of judicial business opened on June 15 1922. The regular sessions provided for were held henceforward and during the years 1922-5 there were nine extraordinary sessions. During the same period the Court heard, considered and gave decisions in six contested international cases and upon 12 requests for advisory opinions. Most of the questions passed upon were novel, difficult and important, and many of them presented differences of opinion which required an authoritative decision if the establishment of peace and order in Europe on a reasonable working basis was to proceed after the extensive re-arrangements caused by the Treaty of Versailles. The 18 judgments and opinions rendered were accepted as final. The existence of the Court is manifestly beginning to affect international discussion of disputes and to be recognised as affording a means of escape from those international deadlocks which have seemed insoluble because neither party felt willing to humiliate itself by surrendering its position.

## IV. EVOLUTION OF THE COURT

The Permanent Court of International Justice is not a product of any one mind or group or negotiation. It is a growth of many years during which a multitude of men familiar with international affairs have collaborated in an effort to adapt to the conditions of international controversy the idea of justice under which in civilised communities judicial decision has superseded private war. Many projects designed to accomplish this result were devised and published by individuals from the 16th down to the close of the 19th century without much apparent effect. In the meantime, however, provisions for arbitration became more frequent in international treaties and the practice of

settling international disputes by arbitration increased. Nineteen international arbitrations are registered during the first half of the 19th century and 117 during the second half. The Hague Conference of 1899 greatly facilitated the practice of international arbitration by providing a general system with well considered forms of procedure, an established secretariat and an available list of suitable arbitrators.

*Justiciable and Non-justiciable Questions.*—The next step in development was a realisation of the distinction between the arbitration of controversies between nations and the judicial decision of justiciable questions. Arbitrators selected *ad hoc* by the parties for the decision of a controversy proved quite likely to negotiate a settlement. Men of the highest character in such a position had a tendency to act under a sense of diplomatic obligation, according to which the legal rights of the parties were merely elements in determining what it would be wise to do. By the time the Second Hague Conference of 1907 met, a considerable opinion had arisen that for the decision of international questions of legal right it was necessary to create a permanent tribunal composed of judges who were judicial officers and nothing else, and who would devote their entire time to the trial and decision of international causes by judicial methods and under a sense of judicial responsibility, and who were so selected that the different systems of law and procedure should be fairly represented.

After very full discussion, the Conference of 1907 declared itself in favour of this view. It adopted a draft project for such a court which, however, remained incomplete because it proved impossible to reach an agreement on the mode of selecting the permanent judges. The numerous smaller Powers were insistent upon their rights of equal and independent sovereignty and upon an equal voice in the selection of judges as a logical incident to that sovereignty. The Great Powers were unwilling to agree to a court in the constitution of which they would have practically no voice commensurate with their populations and interests, as against the overwhelming majority of smaller States. Throughout the Conference and during the seven years that elapsed between 1907 and the outbreak of the World War, there were constant but unavailing negotiations for an agreement upon some mode of electing the judges.

At the close of the War, the Fourteenth Article of the Covenant of the League of Nations required the newly created Council of the League to resume this effort and to formulate and submit to the members of the League for adoption plans for the establishment of a Permanent Court of International Justice. In pursuance of that instruction, 12 international lawyers, resident in as many different countries, were invited by the Council to act as a committee to prepare plans for the establishment of the proposed court. Upon this invitation such a committee met at The Hague on June 16 1920, consisting of members from Great Britain, France, Spain, Belgium, Holland, Norway, Italy, Japan, Brazil and the United States. After long discussion, this committee, on July 24 1920, reported a plan containing the arrangements for the election of judges above described. With some amendments in the Council and Assembly, particularly regarding jurisdiction, that plan was incorporated in the statute of Dec. 16 1920.

Many of the provisions embodied in the statute creating this Court had their origins during these long years of discussion in the necessity of reconciling the opinions of a great number of nations differing in their circumstances, in their modes of thought and feeling and in their conceptions of what would contribute to international justice. The statute probably does not conform to what would be produced in any single country, but it probably does include substantially all the useful provisions upon which the members of the community of nations were willing to agree in the year 1920.

Hudson, *The Permanent Court of International Justice and the Question of American Participation* (Harvard Univ. Press, 1925); Antonio Sanchez de Bustamante, *The World Court* (London, 1925). Several pamphlets on the Court were issued by the World Peace Foundation between 1920 and 1926. (E. Ro.)

**PERNAMBUCO:** see RECIFE.

**PERNERSTORFER, ENGELBERT** (1850-1918), Austrian politician, was born in Vienna April 27 1850. Acquainted since childhood with Viktor Adler, Pernerstorfer studied and sympathised with the young Austrian labour movement since his earliest days as a teacher. In 1870, together with Adler, Friedjung, the historian, and others, he formed a league for the study of social movements. His first political activities were, however, linked with Schönerer's extreme German Nationalist movement. He was one of the authors of the German Nationalist *Liner Programm* (1880), but he left this party and entered Parliament in 1889 as an independent. As deputy he enjoyed the right of free speech and began to act as the mouthpiece of the Social Democrat party, to which he was of the greatest service. He joined the party in 1896, and sat for it in Parliament from 1901 until his death, in latter days being president of its parliamentary fraction and vice-president of the House (1909, 1911). Pernerstorfer was rather an advanced liberal, who adopted Socialism from love of humanity and hatred of absolutism and clericalism. His own principal interests were literary and educational. His fearless and generous personality did much for the poorer classes of his fellow men in days when they were practically political and social outcasts. He died in Vienna Jan. 6 1918.

**PERRY, BLISS** (1860- ), American author, was born at Williamstown, Mass., Nov. 25 1860. He graduated from Williams College in 1881 (A.M., 1883), continuing his studies at the universities of Berlin and Strasbourg. He was professor of English at Williams College, 1886-93, and professor of oratory and aesthetic criticism at Princeton University, 1893-1900. In 1907 he became professor of English literature at Harvard University, and was Harvard lecturer at the University of Paris, 1909-10. He was the editor of *The Atlantic Monthly* 1899-1909.

Among his published works are *The Broughton House* (1890); *The Powers at Play* (1899); *A Study of Prose Fiction* (1902); *The Amateur Spirit* (1904); *Walt Whitman* (1906); *Carlyle* (1913); *The American Spirit in Literature* (1915); *A Study of Poetry* (1920); *Life and Letters of Henry Lee Higginson* (1921), and *The Praise of Folly* (1923).

**PERSHING, JOHN JOSEPH** (1860- ), American soldier, was born near Laclede, Mo., Sept. 13 1860. He studied at the Kirksville (Mo.) Normal School; graduated from the U.S. Military Academy in 1886; was commissioned second-lieutenant and assigned to the 6th Cavalry in a campaign against the Apaches in Arizona. In 1890, during an uprising of the Sioux, he served in Dakota, in charge of the Indian scouts. In 1891 he was appointed military instructor at the University of Nebraska, remaining there four years. He entered the law school and received the degree of LL.B. in 1893. In 1897 he was appointed instructor in tactics at the U.S. Military Academy. He served in Cuba through the Santiago campaign (1898), was appointed ordnance officer with the rank of major of volunteers, and in June 1899, assistant adjutant-general. He organised the Bureau of Insular Affairs in the War Department, of which he was head for several months. In Nov. 1899 he was sent to the Philippines as adjutant-general of the department of Mindanao, and in 1901 was made captain in the regular army and later conducted a campaign against the Moros, which he completed with success in 1903. He then returned to the States and was appointed a member of the General Staff. In 1905 he went to Japan as military attaché to the U.S. embassy, and during the Russo-Japanese War spent several months as military observer with the Japanese Army in Manchuria. As a reward for his success in the Philippines, President Roosevelt in 1906 appointed him brigadier-general from the grade of captain, passing him over 862 senior officers. Afterwards he returned to the Philippines as commander of the department of Mindanao and governor of the Moro Province.

In 1913 Pershing was placed in command of the 8th Brigade at San Francisco, which was soon after sent to the Mexican border. In March 1916 he commanded the punitive expedition into Mexico against Francisco Villa, and the same year was made major-general. After the death of Maj.-Gen. Funston in 1917 he succeeded him as commander on the Mexican border. On America's entrance into the World War he was chosen to command the American Expeditionary Force in Europe. With his staff he reached England June 9, 1917 and four days later landed in France. In Oct. 1917 he was made general. From the start Gen. Pershing insisted upon the integrity of the American Army being preserved. He was convinced that the presence of an independent American Army would be a serious blow to German morale. As commander-in-chief of the A.E.F. he urged the American attack at the Marne salient in 1918, and planned American operations at St. Mihiel and in the Meuse-Argonne. His management of the A.E.F. is clearly described in his succinct *Final Report* (less than 100 pages), issued by the Government Printing Office, Washington, Dec. 1919. His nomination by President Wilson to the permanent rank of general, a grade held previously by only four Americans—Washington, Grant, Sherman and Sheridan, was confirmed unanimously by the U.S. Senate Sept. 1, 1919. In 1921 he was appointed chief-of-staff. He was given the G.C.B. by King George V. He was head of the U.S. deputation which attended the celebration in Peru on Dec. 9, 1924 of the centenary of the battle of Ayacucho, visiting also Chile, Argentina, Brazil and Venezuela. Appointed by President Coolidge as the U.S. representative and *ex-officio* head of the commission to supervise the plebiscite under the Tacna-Arica Arbitration Award, he went to Arica in July 1925 to take up his duties, but, owing to his health becoming impaired, had to resign. He returned to the United States in Feb. 1926. (See TACNA-ARICA.)

**PERSIA (IRAN)** (see 21.187), an Asiatic State under a shah. Its area is about 628,000 sq. m. and the population is estimated at 10,000,000.

## I. POLITICAL CHANGES

**1909-14.**—The autumn of 1909 was a turning point in Persian history. The despotic Mahommed 'Ali had abdicated in favour of his young son Sultan Ahmed, thus ending the struggle against absolutism. Great Britain and Russia were sympathetic, the latter power not only appointing a minister with liberal ideas, but withdrawing her troops from Kazvin and Tabriz. The field was clear, and Persia seemed to have every chance of setting her house in order. But, a year later, the situation again changed, and Nasir el Mulk, who had been elected Regent, reached Tehran at a critical time. The ex-Shah, who had settled at Odessa, crossed Russia with the connivance of Russian officials, and landed near Asterabad with a band of adherents and a quantity of munitions. The Turkoman rallied to him and marched on Tehran, where at first they caused a panic, but were defeated mainly owing to the able handling of a machine gun by a European instructor. The Salar ed Dauleh, brother of the ex-Shah, who had advanced on the capital from Kermanshah with a force of tribesmen, was also defeated. Finally, the ex-Shah retired to Russia because Great Britain refused to consider the question of his return to the throne, which was favoured by Russia.

In March 1912 Russia committed a singularly disgraceful and foolish act at the shrine of the Imâm Riza, the chief centre of pilgrimage in Persia. The Russian consul-general took advantage of minor local disturbances to call in a large Russian force. An *agent provocateur* collected large crowds at the shrine to listen to his incendiary speeches. The Russians then bombarded the shrine. Many innocent men and women were killed or wounded; the sacred tomb-chamber in which lie the remains of Persia's saint was repeatedly struck by shell-fire; the treasury, containing the gifts of countless pilgrims, was removed, and when restored was not intact. The outrage excited intense indignation and was the chief cause of Persia's hatred against

Russia. To cope with the general anarchy, the Persian Govt. engaged a staff of Swedish officers, who began, in the face of great difficulties, to raise a force of gendarmerie. Their first recruits were largely loafers; but they gradually made progress, especially in the capital and in Shiraz. During the World War the force was incorporated with and superseded by the South Persia Rifles raised by Sir Percy Sykes. Events in Persia during the war period, 1914-8, form the subject of a separate article (see PERSIA; CAMPAIGNS IN).

**Events of 1919 and 1920.**—When news of the Armistice reached Tehran, the Persian Govt. hastened to congratulate the victors. In 1919 a Persian delegation reached Paris to lay extravagant claims for territorial expansion before the Peace Conference, but was refused a hearing on the ground that Persia, not having taken the side of the Entente in the War, could not be represented at the conference.

Shortly afterwards, negotiations were conducted between Great Britain and Persia for a convention, which was signed in Aug. 1919. By its terms, Great Britain agreed to help Persia with a loan, with financial advisers and with military officers. It was honestly intended to benefit Persia, but the convention was considered to threaten her independence, and was opposed by the Nationalist party, which was supported by certain allied legations. As a result, when the convention came before the Majlis, it was denounced, and the British incurred much unjust odium, which did little credit to Persia.

In May 1920 the Bolshevik fleet from Baku bombarded Enzeli and occupied Resht, where a Provisional Govt. was formed under Kuchik Khan. At Tehran there was a panic, and the British were blamed for not protecting Persia. The Persian Cossack Division recaptured Resht some months later, but was finally defeated by the Bolsheviks, and took refuge inside the British lines. The corrupt and inefficient Russian officers were dismissed, and were temporarily replaced by British instructors.

**Rise of Riza Khan and Expulsion of the Qajar Dynasty.**—In the winter of 1920-1 a *coup d'état* was organised by a Persian journalist; the Cossack Division marched on Tehran and seized the Government without opposition in Feb. 1921. Their leader was a senior officer, Riza Khan, who had risen from the ranks and was of humble origin. He became commander-in-chief and also Minister of War, and from this date practically ruled Persia. He used the money that reached the treasury primarily for the regular payment of his troops, who realised that their interests were being looked after as never before. He also restored order with the result that Persia became safer than for many years past. For a while Riza Khan contented himself with being the virtual head of the Government but, in the autumn of 1923, he became Prime Minister and drove the *fainéant* Shah out of the country. In the spring of 1924, following the precedent established by Mustafa Kemal in neighbouring Turkey, he attempted to establish a republic with himself as President. This scheme failed, mainly owing to the opposition of the *mullas*, who had noted with deep concern that the establishment of a republic in Turkey was followed by the abolition of the Caliphate. Riza Khan's position was only temporarily shaken by this failure and, in the autumn of 1925, he was able to dethrone the Shah and was elected to the vacant throne by a practically unanimous vote of the Majlis.

Thus fell the Qajar dynasty which had ruled Persia for nearly a century and a half. Since the death of Nasir ud Din in 1896, their rule had been hopelessly corrupt and inefficient. It seemed possible that under Shah Riza Pahlevi, Persia might regain her prosperity and strength. He had organised a well-trained force of all arms, 40,000 strong, with which he defeated and reduced to submission the nomad tribes who, of late years, had been virtually independent of the Government. He then set about disarming the entire population, a step calculated to help materially towards the restoration of order and prosperity.

It might be thought that the hostility of the Qajar Princes would be too strong for the new Shah, but this did not prove the case. Sultan Ahmad had alienated the sympathy of his

relations, many of whom have believed that the bloodless revolution that had taken place was more likely to guarantee them the possession of their wealth than the steady drift towards a break-up that characterised the old order. The chief danger facing the new Shah was that of Bolshevik propaganda, and this was the more grave in that the improved situation depended on the single life of its author. He was also faced with troubles due to the scarcity of bread and the interference with military at elections, which events led, June 1926, to the resignation of the prime minister.

## II. ECONOMIC CONDITIONS

*Communications.*—Persia is cut off from the rest of the world by her rugged mountains and lack of modern communications. A metalled road was constructed during the War by the British from railroad at Khanaqin to Kermanshah and Hamadan, where it joined a Russian built road running to Kazvin and the Caspian. Again, the British opened up routes from Bushire to Shiraz and Isfahan; and from Duzdap, on the border of Persian Baluchistan, to Meshed. These latter roads are not metalled and would not stand heavy traffic. Other routes available for wheeled traffic were opened by the British in Southern Persia, but Persia remains deplorably deficient in roads. Under her American advisers, an effort is being made to grapple with this problem, although the available amount of money is very small. The new Shah is deeply interested in developing a route from Mohammerah *via* Ahwaz, Khurramabad and Sultanabad to Tehran. This all-Persian route runs through fertile districts and it seems probable that it will be selected as the alignment of the first Persian railway. The main road in 1926 was that running from Baghdad to Tehran, and it was being developed by the Eastern Transport Company, which had established a weekly service of cars and lorries from Khanaqin to Tehran, in connection with their service from London to Baghdad *via* Beirut. Thanks to this service, passengers reach Tehran in three days from Baghdad and machinery only takes one month from London, instead of five or six under the old conditions.

With the exception of the almost derelict line from Julfa there are no railways in Persia, whose communications are actually deteriorating relatively to progress in neighbouring countries. Indeed, until a railway programme is carried out, Persia will remain a mediaeval land. Persians hope to finance railway construction by extra taxes on tea and sugar, but the sums raised would not be sufficient for the purpose. Railways would not pay in Persia and will have to be subsidised by the Government.

The Persian Army is developing an air service of its own, which has helped materially in the restoration of internal order. The country is particularly suitable for transit by air and the important British commercial air service that is being organised between Baghdad and Karachi will follow down the shores of the Persian Gulf. A German company has been granted the privilege of establishing an air service in Persia.

Persia is well served by telegraphs. The Indo-European trunk lines run from Julfa to Tabriz, Tehran and Kashan. At this town, one line runs due south to Bushire and thence by cable to Jask and by land line to Karachi, while a second line runs through Yezd and Kerman and across Baluchistan to Karachi. Other lines also exist. Wireless installations are being constructed in the vicinity of Tehran and it is intended to erect smaller installations at other centres. Telephones are installed in the chief towns.

*Agriculture.*—Persia is essentially an agricultural country. The main crops are wheat, barley, millet, cotton, opium, lucerne and tobacco. Sesame and other oil seeds grow everywhere, as do onions and turnips. Rice and maize are chiefly produced in the Caspian provinces. Potatoes, beans, peas, cabbages, tomatoes, cucumbers, spinach, lettuces and radishes are the chief vegetables, but many of them, potatoes for example, are only grown near the larger towns. Persia is rich in fruit, which grows to considerable perfection in spite of the lack of scientific cultivation. Apples, pears, quinces, apricots, plums, peaches,

nectarines, cherries and mulberries grow everywhere in great abundance. Figs, pomegranates, almonds and pistachio nuts grow better in the warmer districts, while the date-palm, orange and lime are, generally speaking, confined to the *garmsir* or "hot country." The grapes and melons of Persia are famous. The barren mountains produce an edible thistle, rhubarb and a large mushroom. The delicious manna exudes from a species of tamarisk, while valuable gums are tapped from stunted trees. Tea planting was started some years ago in the Caspian provinces and is making some progress, while the silk industry is capable of considerable development. Generally speaking, agriculture has been utterly neglected, and although it may be difficult to increase the supply of irrigation water on the plateau, the value and output of the crops could be considerably increased by the application of modern methods.

*Finance.*—With the help of her American advisers, Persia is now producing honest budgets. For the year 1923-4 the revenue was £5,128,000, Customs representing 33%, direct taxation 16% and oil royalties 10 per cent. The expenditure was £5,700,000, of which 40% was taken by the War Ministry. For the year 1924-5 the incomplete accounts show that this deficit had been practically wiped out. After the War the Bolshevik Government cancelled all debts due by Persia and all Russian concessions. These debts had been larger than the sums owed to the British Government and to the Imperial Bank of Persia, which amount to about £2,600,000. This small debt, to some extent, represents advances which are repaid during the year. Persia has kept faith with her creditors, thereby strengthening her financial position against the day when she will need to float a large loan for the reconstruction of the country.

The Imperial Bank of Persia, a British institution, is the state bank, receiving revenues and remitting Government funds without charge. It also accommodates the Treasury with advances and in many other ways. It possesses the monopoly of issuing notes and pays the Government 6% of its profits. The Imperial Ottoman Bank has several branches in Persia, and banking is also carried on in a small way by Persian *sarraf*s. The standard coin is the silver kran, the conversion rate used in this article being krs. 45 to £1. Gold is also minted, but has no fixed prices and fluctuates considerably in value. It is especially high at the Persian New Year (March 21), at which season gold coins are given as presents.

*Trade.*—Persian imports for 1923-4, aggregating kran 694,251,000, consist of manufactured products 54%, and food and drink 33 per cent. Exports valued at kran 768,392,000 include raw or semi-manufactured materials 72%, and manufactured articles 17 per cent. The above figures prove the undeveloped state of Persia, dependent on foreign countries for her manufactured articles, a large proportion of which are textiles, tea and sugar. Of her exports, mineral oil constitutes one-half, followed by opium, carpets, cotton and wool. Before the War, the trade of Russia reached 60% of the total trade, as against 21% for the British Empire. To-day the position is reversed, Great Britain's share being 57% and that of Russia 18 per cent.

*Anglo-Persian Oil Company.*—Persia possesses considerable mineral wealth but, owing to lack of railways, water, fuel and technical skill, it remains undeveloped. The notable exception is the British oil concession which includes all Persia except the five northern provinces. The royalties derived from the company constitute 10% of the revenue, and mineral oil forms one-half of the exports. Moreover, the company spends over £2,000,000 in Persia and trains some 40,000 Persians to habits of industry. Opium is grown in almost every province and comprises about one-fourth of the export trade. The Persian Government is prepared to limit the export, but the question bristles with difficulties. The League of Nations is sending a Commission to inquire into the whole question, but it is unlikely that they will be able to recommend the substitution of other crops owing to the absence of railways. To conclude, there is great need for modern means of transport and for education of

every sort, without which Persia must inevitably remain a poor and undeveloped country.

Hall, *Ancient History of the Near East* (1913); Sir P. Sykes, *History of Persia* (2nd ed.) (1921). (P. M. S.)

**PERSIA, CAMPAIGNS IN.**—For many years before the World War Germany had been making strenuous efforts to increase her influence and interests in Persia. At Tehran a college was opened, staffed by German professors and subsidised by the Persian Government. In the Persian Gulf the firm of Wonckhaus began to deal in mother-of-pearl at Lingeh in 1896; in 1897 a German vice-consulate was opened at Bushire. In 1900 Germany attempted to purchase a site for the terminus of the Baghdad railway at Al Kuwait, but Sheik Mubarak had previously concluded a secret treaty with Great Britain agreeing, in return for protection, not to sell or lease any of his territory without her consent.

Other German efforts, made in collusion with Turkey; members of Mubarak's family and the Wahabis, failed; but Turkey established and held posts on Mubarak's territory in Hor 'Abdullah, an inlet running from behind Bubiyan Island to within 30 m. of Basra. In 1902 the firm of Wonckhaus attempted to gain control of the pearl fisheries around Hulul, then of the red oxide deposits of Abu Musa and finally of a piece of land along the river bank at Mohammerah. These attempts were foiled by Sir Percy Cox, the British Resident. In 1906 the Hamburg-Amerika Co. started a service to the Persian Gulf. At the outbreak of war Great Britain was engaged in negotiations with Germany which would have given that Power a strong position at Basra, the destined terminus of the Baghdad railway; and had acknowledged Turkey's suzerainty over Al Kuwait.

### I. THE MENACE TO INDIA

In July 1914 the regency terminated with the coronation of the young Shah, who had hardly taken up his duties when hostilities commenced. His Majesty summoned the Majlis, and duly proclaimed the neutrality of Persia. The position was, however, a difficult one. The grandees were, in many cases, only anxious to receive money from one or both sides; the masses hated the Russians and mistrusted the British for being the friends of their enemies. There was sympathy in some quarters for the Turks, and "let the Christians devour one another" was frequently heard. But Persia was powerless. Her military forces included the Cossack brigade 8,000 strong, the Swedish gendarmerie 7,000 strong and the useless Persian Army.

*German Policy in Persia.*—At first sight it would seem unlikely that remote Persia should become a war theatre, but there is no doubt that Germany had prepared her plans for attacking the Indian Empire across Persia, using the Turkish Army as her instrument. Before Turkey declared war, the Government of India took the precaution of despatching a brigade of Indian troops to the Bahrein Islands. After the outbreak of hostilities this force, increased to a division, defeated the Turks at Sahil, and occupied Basra on Nov. 21, thus effectually protecting the oil refineries of the Anglo-Persian Oil Co. To protect the pipe-line, 150 m. long, running through Ahwaz to the oilfields at Maidān-i Naftūn, which the tribesmen had breached and fired in several places, operations were undertaken, as a result of which Persian soil was cleared of a Turkish force that threatened Ahwaz; the local tribes then submitted to the Indian troops and the pipe-line was repaired.

Germany hoped to embarrass Russia, and still more, Great Britain, by forcing Persia and Afghanistan into the War on her own side and creating disturbances in India and on her frontiers. If Persia would come in, the claim that Islam was on the side of the Central Powers might have brought in Afghanistan. Germany was able to divert forces to Persia at a small cost; for India was weakly held, and the "Emden" was causing some uneasiness. A Turkish force marching across Persia to Afghan-

istan could have forced its Amir to join an invasion of India. Agents well furnished with arms and money were sent to enlist levies and march across Central and Southern Persia, murdering or expelling the British. These groups formed supports to missions destined for Afghanistan and Baluchistan, which bore official letters to the Amir and Indian princes and carried on an anti-Christian propaganda in the name of the "Hajji Wilhelm."

The chief German agent was Wassmuss, formerly consul at Bushire, who organised an anti-British confederacy at Tangistan, Dashti and Dashtistan, bought over the Swedish officers of the gendarmerie at Shiraz and secured control of their force. The British vice-consul was murdered, the consul and entire colony arrested and taken to the coast, Quawam el Mulk, the chief of the Arab tribes, who was acting Governor-General, was driven out, and Wassmuss reigned supreme in Fars. In Kermanshah, Turks and Germans expelled the British in April 1915; at Isfahan the Germans were equally successful, and later at Yazd and Kerman. At the end of 1915 seven out of the 17 branches of the Imperial Bank of Persia (a British company) were in enemy hands, and the British colonies had been expelled from Central and Southern Persia, except the Gulf ports. In the north the position was different. The Russians landed troops at Enzeli, which marched on Tehran. This action drove the enemy ministers to quit the capital. They tried, in vain, to induce the Shah to accompany them. They used the force they had collected, mainly composed of escaped prisoners-of-war, for somewhat aimless raiding, but it was easily dispersed by the Russians who moved south and occupied Kashan.

One of the dangers to be guarded against was that of German missions to Afghanistan and Baluchistan. Efforts were made to intercept such parties, but it took time to make the necessary arrangements, and it was not until 1916 that the Eastern Persian cordon was in working order with the Russians patrolling the frontier as far south as Kain, from which centre the British, with some regular troops and a number of locally raised levies, were responsible to the borders of Baluchistan. Persia being a land of vast distances, it is not surprising that a German mission was able, by means of very long marches, to reach Herat in safety. It was received with every honour, but displayed extraordinary lack of tact by openly decrying everything of Afghan manufacture, the arms manufactured at the arsenal at the capital, for instance, being criticised contemptuously. At Kabul too, the same behaviour brought the mission into trouble. The Amir, who had received it courteously, played for time by summoning a council representative of all the tribes and by lengthy meetings with the mission and his own advisers. The Germans gradually realised that, without a Turkish force, their efforts were wasted. They were finally dismissed, the Amir pointing out that he could hardly break with the British until a large, well-equipped army reached Kabul from the west. The mission broke up into small parties, most of which successfully evaded the cordon.

In 1916 the ebb and flow of the struggle were very marked. At first the Turks, shortly after the retreat of the British from Ctesiphon, occupied Kermanshah and pushed forward towards Hamadan. The Russians in their turn, justly elated at their astounding feat of arms at Erzerum, advanced and drove the enemy off the plateau, while a second force swept the hostile Bakhtiaris out of Isfahan and brought back the British and Russian communities. The capture of Kut again transformed the military situation and, in the summer, the Turks, 16,000 strong with 54 guns, gradually drove back the Russians who could only oppose them with 12,000 men and 19 guns. Kermanshah was evacuated and then Hamadan, the retreat continuing as far as the Sultan Bulaq range which covered Kazvin and threatened a force marching on Tehran. This situation remained unchanged until December.

*The South Persia Rifles.*—In 1916 it was decided, in consultation with the Persian Govt., to organise a force of Persian troops to restore order in Southern Persia and take the place of the Swedish gendarmerie. This force was to be 11,000

strong, and the Cossack brigade was to be raised to a similar strength. Brig.-Gen. Sir Percy Sykes, who had spent many years in Southern Persia, was appointed to undertake this task, and landed at Bandar 'Abbas in March, with three other British officers and a few Indian instructors. The state of affairs was most unfavourable as, apart from the defeat of Qawam, the British agent and his escort were assassinated at Lingeh, and two British officers were assassinated in Makran about the same time, both murders being due to German instigation; and finally this terrible month of April saw the grave disaster of Kut al Imara. Many experienced officials expected a wave of fanaticism to sweep across Persia and there was certainly cause for deep anxiety, especially in Makran, but British coolness undoubtedly saved the situation. Recruiting operations at Bandar 'Abbas were started immediately after landing and, in spite of a strong anti-British party, men were rapidly enlisted, and, before the end of a month, the Persian flag was hoisted with ceremony over a camp. The force, handled with much tact and patience by its British and Indian instructors, never looked back, and was soon able to protect Bandar 'Abbas and an important section of the caravan route from the raiding tribesmen.

Qawam was aided by the British with money and munitions, and an exaggerated report of the means placed at his disposal led to the rebel Arab headmen kissing his feet. With their aid he defeated the Swedish gendarmerie, and was marching in triumph to Shiraz when he was killed by a fall from his horse. His son, a man of 28, was, however, able to restore Persian authority in Fars.

The success of Qawam and the landing of the mission at Bandar 'Abbas made the position of the German parties at Kermān decidedly insecure. The governor-general became hostile to them, and they decided to retire westwards to Fars, the route farther north being dangerous owing to the Russian advance southwards. They fled in two parties, and after suffering some losses from attacks on the road, they were all captured by Qawam and imprisoned at Shiraz. The little band consisted of 60 Germans and Austrians, a dozen Turks and a few Afghans.

A small force of Indian troops, consisting of a section of mountain guns, a squadron of cavalry and 500 rifles, was sent to Bandar 'Abbas, and Sir Percy Sykes marched inland a distance of 280 m. to Kerman, where he was received with much cordiality. The various pro-German elements who had created a state of insecurity fled, the bank and telegraph offices were reopened, and the normal state of affairs was quickly re-established. The column then marched to Yazd, where the British colony had just returned. News being received of the Turkish advance and of a probable attack on Isfahan, the column made a forced march to that city where it joined the extreme left of the Russian Army, represented by 600 Cossacks. The Turks, hearing of the arrival of the British at Isfahan, stopped at a village some six miles distant, and then retired. When it became evident that the danger had passed, the column marched south to Shiraz, which it reached in Nov., thereby completing a march of 1,000 m. through the heart of Persia.

At Shiraz the question of the gendarmerie had to be settled. The Persian Govt. had not actually given its consent to its being incorporated in the South Persia Rifles, but it was unable to pay or equip the force. Spread over the route for a distance of 200 m. from the borders of Fars in the north, to Kazerun in the south, and numbering some 3,000 men, the problem which confronted Sir Percy Sykes was one of extreme difficulty. He had no staff to administer or train such large numbers, and he was aware that it was this force which had seized the British consul only a year previously and that many of the officers were pro-German in sentiment. But he also realised that, if the gendarmerie broke up into well-armed bands of robbers and devastated the country, few supplies would reach Shiraz. He consequently decided to take over the entire body, and the force gradually developed and helped to restore order in South Persia. (See WORLD WAR; WORLD WAR: BIBLIOGRAPHY.)

## II. THE BRITISH IN PERSIA

During the winter, however, the positions in Mesopotamia entirely changed. Instead of weak, ill-equipped columns, severely handicapped by unfavourable climate conditions, failing before Kut al Imara, there was the pleasant picture of overwhelming forces under the inspiring leadership of Gen. Sir Stanley Maude recapturing Kut in Feb. 1917 and following this up by the signal success of the capture of Baghdad. The position of the Turks in Persia became more and more difficult as the British advanced. On the day Baghdad was occupied they evacuated Kermanshah and, pursued by the Russians, reached the Persian frontier at Qasr-i-Shirin on March 31, worn out and hungry but not wholly demoralised. But during the succeeding winter, the Russian Army disintegrated. Its collapse opened up to the enemy a completed line of northern advance across the Caucasus and the Caspian Sea to 'Ashqabad, Merv (the junction for Kushk, within striking distance of Herat), Bukhara, Samarqand and Tashkent, the administrative centre of Russian Turkistan. Over 100,000 German and Austrian prisoners were in Central Asia and if through communication had been established, it would have been easy to reorganise these veterans and march on Kabul, with an invitation to the Afghans to share in the plunder of India. In Sept. 1917 Georgia and Armenia decided to claim their independence, and a third state came into being under the title of the republic of Azerbaijan, with Baku as its capital. In connection with the efforts made to ward off the danger to India involved in the Russian collapse, British troops entered Western Persia.

*The Dunsterville Mission.*—It was out of the question to dispatch large bodies of troops to support the Georgians or Armenians, as Baghdad was 800 m. distant from Baku. The authorities therefore, decided to dispatch a military mission to reorganise the sound elements of the country into a force that would prevent the Turks and their German masters from reaching Baku. It was hoped that these small States would fight for their homes, but the Armenians absolutely failed to do this. Maj.-Gen. L. C. Dunsterville was appointed to command this mission, and, in Feb. 1918, he started off from Baghdad with a party of officers in 40 cars to cross northwest Persia. Enzeli was his objective, and he hoped from that port to be able to proceed to Baku and Tiflis. He reached Enzeli only to find that the port and its shipping were in the hands of hostile Bolsheviks, while the neighbourhood was dominated by Mirza Kuchik Khan, an ambitious brigand who had recruited some 4,000 followers, nicknamed *Jangalis* or "Forest Dwellers," to the cry of "Persia for the Persians," and who robbed his countrymen if they refused to join him. Dunsterville quickly realised the situation, and, before his opponents had concerted their plans and had overcome their fear of the armoured motor-car, the mission had retired to Kazvin and Hamadan, which latter city became its headquarters.

During this period, Dunsterville was brought into close relations with the Russian generals Baratov and Bicherakov. The former had commanded the Russian troops in Northern Persia and was now helplessly watching their disintegration. The latter, on the contrary, had kept his command of 1,200 men practically intact. By March the last of Baratov's men had left, but Dunsterville had been able to keep Bicherakov's command at his side. Without its aid, the *Jangalis*, elated by the retirement of the mission, which was magnified into a great victory over a British army, would have been able to march on the capital. There they would probably have introduced a reign of anarchy and have forced Persia into the War on the side of the Central Powers, with whom Kuchik Khan had close relations; he also had German, Austrian and Turkish instructors well supplied with machine-guns. When the *Jangalis* marched on Kazvin, Bicherakov forestalled them, and drove them back to the forests with heavy losses. He then embarked at Enzeli. Dunsterville, who had received reinforcements consisting of a regiment of cavalry, a battery and two regiments of infantry, followed behind Bicherakov and took over the road. The *Jangalis*, under their European officers, attacked a detachment

at Resht, but suffered heavy losses, and Kuchik Khan made terms and became a contractor for supplies. About this time the Bolshevik Govt. at Baku was overthrown and replaced by the Central-Caspian dictatorship, which asked for British assistance. Dunsterville took his force to Baku, held it for some weeks against overwhelming Turkish numbers, denying the use of the oil wells to the enemy, whom he also kept away from the Caspian Sea, and finally evacuated the town and returned to Enzeli, thus ending a very gallant episode of the War.

*Investment of Shiraz by the Kashgais.*—In the spring of 1918 the Persian Govt., in reply to a British note, denounced the South Persia Rifles as a foreign force and a threat to Persian independence and integrity. It also expressed the hope that the British Govt. would withdraw its troops and allow Persia to commence her cherished reforms.

The Cabinet was under the impression that Germany was winning the World War or such a curt note would never have been penned. This reply was published all over Southern Persia; and the results were speedily shown in serious desertions from the South Persia Rifles and culminated in the formation of a confederacy under the Kashgai chief, Solat-u-Daulah, to annihilate the British in Southern Persia. He had at his disposal 4,500 Kashgais and 1,500 Kazerunis and this number was reinforced by contingents from Dashti, Dashtistan and elsewhere, and reached about 8,000 fighting men. The tribesmen were well armed with Mausers, had plenty of ammunition, and fought both bravely and cunningly. The British force at Shiraz was 2,200 strong, one-third being recruits. The South Persia Rifles slightly outnumbered the Indian troops and, owing to propaganda and the proclaimed hostility of the Persian Govt., were a danger to the British. The detachments in the outposts mutinied and surrendered or deserted. Qawam had collected 2,000 Arabs in and about Shiraz, who were ready to attack the beaten side. On May 24 the column marched out 1,600 strong and defeated the Kashgais in the hilly country to the west of the city. About 10 days later the enemy returned in still larger numbers, and the Kazerunis occupied the garden quarter, which almost touched the fortified perimeter constructed by the British outside Shiraz. The inhabitants of Shiraz were incited against the British by the *mullas*, some of whom preached *jihad* or Holy War.

Sir Percy Sykes learned that the Kashgais were preparing to unite with the townspeople in a combined attack on June 17, and he determined to forestall them. Accordingly, on June 16, the column sallied out and again inflicted considerable losses on the enemy. On the following day, Shiraz rose, its inhabitants attacking everyone suspected of being friendly to the British. But the Kashgais did not come to the support of the townspeople, who were overawed by the seizure at midnight of various key-positions by the British. The tide then turned. The governor-general appointed a new *Ilkhani* or "paramount chief" in place of Solat, whose followers began to break away, influenced by the heavy losses they had suffered. Qawam declared in favour of the new *Ilkhani*, and his example was followed by a brother of Solat and by perhaps one-quarter of the tribe. The column marched out again, and Solat fled a broken man, pursued by Qawam, the new *Ilkhani*, and most of the Kashgai tribe. The expedition is described by L. C. Dunsterville, *The Adventures of Dunsterforce*, 1920. (P. M. S.)

**PERSIAN GULF** (see 19.974).—This term is, strictly speaking, restricted to the land-locked sea which extends from the mouth of the Shatt al 'Arab 460 m. to the mountainous promontory of Ras Musandam, but for the purpose of this article it will be considered to include the Gulf of Oman to which it is joined by the Strait of Ormuz, 29 m. wide. The Gulf itself has an average width of 120 miles. It is tidal, spring tides rising about 9 ft.; with the exception of the Shatt al 'Arab almost all the streams that flow into it are so salt as to be undrinkable. Good harbours are scarce, with the exception of Al Kuwait and Muscat, anchorage being mostly shallow and exposed.

*Political History.*—Up to 1913 the Turks exercised suzerain rights in the maritime tracts of Al Hasa and Hofuf and claimed

it in Qatar and Al Kuwait. The Sultan of Nejd, 'Abd el 'Aziz ibn Sa'ud, ejected them from the first-named districts; the World War put an end to their claims elsewhere in the Gulf. The Trucial chiefs of the Arabian coast hold sway from Ras Musan dam to Qatar. From east to west their headquarters run as follows:—Ras al Khaima, Umm Qaiwain, 'Ajman, Sharja, Dibai, Abu Dhabi, Qatar. The Sheikh of Bahrein exercises no authority on the mainland.

The friendly attitude of Ibn Sa'ud towards Great Britain on the outbreak of the War resulted in the conclusion of a treaty with him dated Dec. 28 1915, in which he was recognised as independent ruler of Nejd and Al Hasa, and given a limited dynastic guarantee, with a promise of support in case of foreign aggression. Great Britain assumed control of his foreign relations outside Arabia. He on his part undertook not to alienate any territory to a foreign power, except with the consent of the British Government.

*British Interests.*—The peculiar interests, strategic, political and commercial, of Great Britain in the Persian Gulf have never been denied. The considered policy of the British Govt. was embodied in 1903 in Lord Lansdowne's declaration in the House of Lords:—

We should regard the establishment of a naval base or of a fortified port in the Persian Gulf by any other Power as a very grave menace to British interests, and we should certainly resist it by all the means at our disposal.

This declaration was formally reaffirmed in 1907 by Sir E. Grey in a dispatch to the British Ambassador at St. Petersburg, which further stated that:—

H.M.'s Government will continue to direct all their efforts to the observance of the *status quo* in the Gulf, and the maintenance of British trade; in doing so, they have no desire to exclude the legitimate trade of any other Power.

These declarations were never challenged, and the policy indicated has been steadfastly followed by successive governments.

*Arms Traffic.*—The arms traffic was rife in 1911, in spite of a naval blockade of the Makran coast by Great Britain in 1910-11. In 1912 the Sultan of Muscat issued a proclamation requiring all arms imported into Muscat to be placed in a special warehouse. This killed the trade at Muscat and, by 1913, it had virtually ceased to exist.

*Slave Trade.*—In 1833 the status of slavery was abolished throughout the British Empire. Great Britain, in defiance of her commercial interests and her popularity with the Moslem populations of the Gulf, set herself to suppress the trade in these waters, an arduous task involving great sacrifice of life and money. By 1920 the last remaining traces of the traffic by sea had virtually disappeared, but domestic slavery as an institution is likely to continue in Muscat and in Central Arabia; it is important to distinguish domestic slavery, which is an institution recognised by Koranic law, which imposes many obligations and restrictions on the owners of slaves, from the commercialised slavery which disgraced Christendom in the 18th and the early days of the 19th century.

*Trade.*—The Persian Gulf serves as a means of communication for two land masses, *viz.*, Persia and Arabia. In both, the population is small and poor, so that the commerce of the region is of comparatively small aggregate value. The principal port is Bushire on the Persian side; the others, in order of importance, are Mohammerah, Bahrein (Manama), Bandar 'Abbas, Al Kuwait, Muscat and Lingeh.

Since the standard of living of all the peoples round the Gulf is low, their requirements are few; cotton piece goods, tea, sugar and foodstuffs are the principal imports. The total value of goods imported into the Persian Gulf in 1924 was about £8,500,000 sterling—including piece goods to the value of £2,000,000, sugar £1,500,000, rice £750,000, tea and coffee £500,000. Of imports, over 50% are from India and 25% from the United Kingdom, but a large proportion of India's share consists of goods in transit from Europe and the United Kingdom.

The exports for 1924 were estimated at £12,500,000 sterling, including the Anglo-Persian Oil Company's exports valued at £8,000,000, opium £1,250,000, pearls £500,000 (probably greatly undervalued), carpets £250,000, dates £250,000. Of exports (including petroleum products) the United Kingdom in 1924 took about 50%, India 18%, Russia 8% (mostly opium).

*Communications.*—The only steamship line (1926) running regular services to the Gulf ports is the British India Steam Navigation Co., Ltd. The next line of importance is run by Messrs. F. C. Strick and Co. Ltd., who maintain a direct service with the United Kingdom to the Persian Gulf. There is of course constant communication between various ports by native craft. When once merchandise has

arrived at any port, the further transport to the hinterland is effected by pack animals.

The following table shows the amount of shipping entering the Shatt al 'Arab during the three years:—

|        | Gross registered tonnage | No. of steamers |
|--------|--------------------------|-----------------|
| 1922-3 | 2,581,855                | 530             |
| 1923-4 | 2,776,052                | 636             |
| 1924-5 | 3,197,046                | 601             |

of which about 75 % were tank steamers proceeding to Abādān for oil, of which some 4,000,000 tons were exported in 1924-5.

The bar of the Shatt al 'Arab is being dredged by the 'Iraq Govt., and it is intended to maintain a minimum depth of 27 ft. at high water, along a dredged channel 12 m. in length. Lights and buoys are maintained at certain ports and on certain islands in the Persian Gulf by the British Govt., the cost being met (since Oct. 1925) by a levy on all ships crossing the bar of the Shatt al 'Arab.

**Currency.**—On the Persian side the unit of currency is the *kran* (roughly equal to 6d.); the rupee is also current. On the Arabian side the rupee is in general use; inland the Maria Teresa dollar (roughly equal to 2s. 6d.) is in use.

**BIBLIOGRAPHY.**—D. G. Hogarth, *The Nearer East* (1902); L. Fraser, *India under Curzon and After* (1911); S. B. Miles, *The Countries and Tribes of the Persian Gulf*, 2 vol. (1919); Sir P. Sykes, *A History of Persia*, 2nd ed., 2 vol. (1921); H. St. J. B. Philby, *The Heart of Arabia*, 2 vol. (1922); See also: Admiralty, *Notes on Climate and other subjects in Eastern Mediterranean and adjacent countries* (Naval Intelligence Dept., 1922); Geographical Journal: for Nov. 1923, R. E. Cheesman, "From Oquir to the Ruins of Salwa," vol. lxii., No. 5; and Feb. 1925, "The Deserts of Jafura and Jabrin"; March 1925, A. T. Wilson, "The Delta of the Shatt al 'Arab and proposals for dredging the Bar," vol. lxx.; Sept. 1925, P. C. Cox, "Some Excursions in Oman." (A. WIL.)

**PERTAB SINGH, SIR** (1844-1922), Indian soldier and statesman (see 21.259), relinquished his position as Maharaja of Idar in 1911 in favour of his adopted son Daolat Singh, in order to resume the regency of Jodhpur which he had previously held on the death of his brother in 1895, but this time for his grand-nephew Summair Singh, then 13 years of age. When the World War broke out Sir Pertab, in the words of Lord Hardinge the Viceroy, "would not be denied his right to serve the King-Emperor in spite of his 70 years." He came to France for service in the field with his young ward, then only 16, and commanded the famous Jodhpur Lancers. In the later stages of the War he served with them in Egypt and Palestine. Sir Summair Singh died in 1918, two years after receiving ruling powers, and Sir Pertab again became regent, assisted by a council. He died on Sept. 4 1922, after nearly 60 years of close association with the administration of Jodhpur.

**PERTH, Australia** (see 21.259), the capital of Western Australia, had a population of 154,873 in 1921 within a 10-mile radius, which included the port of Fremantle and 129,339 in the city proper. Perth is linked to Brisbane by the railway opened in 1917 from Port Augusta to Kalgoorlie. The tramways were transferred to the Government in 1913 and are now worked in connection with the railways. A comprehensive scheme for supplying water to the metropolitan area was undertaken in 1922. The University of Western Australia was inaugurated in 1913 and a branch of the mint was established here in 1916.

**PERTH, Scotland** (see 21.260), with an area of 2,653 ac., had a population of 33,208 in 1921, showing a small decrease on the figures for 1911. The city has been in the Perth and Kinross division for parliamentary purposes since 1918. In 1910 the west tower of the cathedral, which had been left unfinished owing to the insecure state of the foundations, was taken down. A city hall in King Edward street was finished in 1911, and a replica of the old market cross, destroyed in 1765, was unveiled in the open space opposite the hall in 1913, as a memorial to King Edward VII. New buildings for the Perth Royal Infirmary were opened on the slope of a hill to the west of the city in 1914. The Perth Academy and Sharp's Institute were combined in 1915. The museum of the Perth Literary and Antiquarian Society has been handed over to the municipality and reorganised. Kin-noull Hill, a landmark overlooking Perth, was presented by Lord Dewar in 1924. The restoration of the church of St. John the Baptist was undertaken as a War Memorial.

**PERU** (see 21.264), a republic in South America, and a member of the League of Nations. The estimated area was 532,000 sq. m. in 1925. No census has been taken, but the population in 1925 was estimated at 4,750,000, consisting of Indians 52%; Mestizos, 30%; Asiatics, negro-Indians, etc., 10%; pure negroes of African origin, 6%; and whites (Caucasian), 2%. The chief towns and their population (1925 estimate) are: Lima and suburbs 225,000; Arequipa, 55,000; Callão, the principal port, 60,000; Cuzco, 35,000; Trujillo, 25,000; Iquitos and Ayacucho, 20,000 each; and Chiclayo, 30,000.

## I. POLITICAL HISTORY

The presidential term of Don Augusto B. Leguia y Salcedo, 1908-12, was notable for many internal reforms and improvements, including the planning of the Ucayali Railway and the settlement of old boundary disputes with Bolivia and Brazil. A policy of naval reform and commercial development was interrupted by the collapse of the rubber market, which caused a financial stringency. At the expiration of his term of office in 1912, Leguia was succeeded by Don Guillermo Billinghurst, the grandson of an English officer. The Conservative party did not, however, approve Señor Billinghurst's parliamentary reform policy, and a military *coup d'état* led by Col. Oscar Benavides resulted in his removal from office and deportation in Feb. 1914. Benavides remained in the presidency until July 1915. Each of these presidential terms was revolutionary in character and there was general political uneasiness, accentuated by acute diplomatic controversies with Ecuador and Bolivia.

**The War Period.**—The outbreak of the World War found Peru passing through a period of economic and financial difficulty, which continued until the end of 1915, when the demand for Peruvian cotton, sugar, copper and other products at war prices greatly relieved the situation. Dr. José Pardo entered upon his second presidential term in July 1915. Public opinion was divided as to the attitude to be adopted by Peru towards the War. A section of the Conservative aristocracy was at first inclined to favour the Central Empires, partly because of a dislike of President Wilson's utterances, but mostly because of financial and sentimental ties with Germany. On the other hand the majority of the intelligentsia strongly favoured France and her allies, and this element finally caused the severance of diplomatic relations with Germany in 1917, soon after the declaration of war by the United States. The years 1916, 1917 and 1918 were remarkable in that, whereas trade and industry enjoyed the greatest boom known since the foundation of the Republic, the national finances did not improve to a corresponding degree—largely owing to the need for a thorough overhauling of the administration, which the complexities of local politics prevented the President from effecting. On several occasions minor crises occurred, the most notable being in 1918 when members of the military garrison of Ancon revolted and caused a good deal of damage, which included the cutting of the railway, before they made their escape to the interior.

**Post-War Developments.**—Early in 1919 Señor Augusto B. Leguia returned from England and announced his intention of again standing for the Presidency. On May 18 the election took place without disorder, but before the results could be declared a *coup d'état* on July 4, unaccompanied by violence, placed Leguia in the chief executive office. The new President issued a manifesto declaring that an attempt to deprive him of a victory at the polls had compelled him to seize the direction of affairs and he proposed to introduce constitutional reforms which would render personal and autocratic government impossible. On July 10 a decree was issued authorising the formation of a Constituent Assembly for the purpose of altering the existing constitution. This body formally opened on Sept. 24 and passed a law giving legal sanction to all the Acts and Degrees of the Provisional Government. Señor Leguia was inaugurated as constitutional president on Oct. 12 1919; and by the end of the year the constitutional reforms he had proposed were referred to a plebiscite, and accepted almost in their entirety. The chief reforms proposed were:—

1. An increase of the presidential term from four to five years, and the re-election of an entirely new Congress for the same period, instead of for two years as hitherto;
2. A Council of State, consisting of six members to act in an advisory capacity to the President to be provided for;
3. The reorganisation and decentralisation of provincial government, and the formation of three regional legislatures;
4. Income tax, hitherto unknown, to be introduced;
5. Government officials debarred from drawing salary from more than one post at the same time; and
6. Labour disputes to be settled by compulsory arbitration.

Some of these reforms did not immediately materialise; others were introduced before the end of 1919. At the beginning of Dec. the Assembly authorised the dissolution of all municipal bodies, and the appointment, by the executive, of new ones. On Dec. 26 a law was passed empowering the Government to confiscate the property of persons attempting a revolution. The general prosperity of the country helped the opening period of Leguía's administration, and, although the masses were fervently in his favour, his opponents were of opinion that his proposals for legislative reform and agricultural, commercial and industrial developments, were much too ambitious to be immediately successful. In 1920 the new constitution drawn up in 1919 was published, and throughout the year the President's reformist efforts were continued with unabated zeal.

The years 1920 and 1921 (up to the month of August) showed a continuance of his original policy, often interrupted by acrimonious discussions in Congress and by spasmodic attempts at obstructionism here and there by the President's political enemies. On Aug. 5 an insurrectionary movement described to be for the purpose of "constitutional restoration" was initiated by a Captain Cervantes in the Department of Loreto. This movement spread to the departments of San Martín and Amazonas; and although the government sent small bodies of troops, isolated risings on a small scale continued among the Indian population and in the south. The rising was not finally suppressed till late in 1921. During this ineffective revolt the Peruvian and Brazilian Governments exchanged notes in regard to a request by Peru that navigation should be stopped between Manaus in Brazil and Iquitos in Peru, following upon the closure of this port by a decree of Aug. 10.

The years 1921, 1922 and 1923 were marked by an acute financial and economic crisis caused by a collapse of the abnormal prosperity induced by the World War, to be followed by a slow and gradual process of readjustment that was well on the way to completion by 1924. In that year the Government, although still hampered by lack of funds, had succeeded in effecting many improvements in administration. Don Augusto B. Leguía was again elected to the presidency in 1924, this time unopposed by the votes of the Democratic, Democratic Reform and Constitutional parties, for the period 1924-9, during which he proposed to continue his reforms. In May 1924 preparations were made for the election of a new Congress, and the Cabinet was reconstituted with Dr. Alexandrino Maguina as President of the Council. From then onwards till the end of the year governmental and public attention was directed towards preparations for the celebration of the Centenary of Ayacucho in Dec., to commemorate the final struggle against Spain which culminated in the independence of Peru and the Spanish-speaking republics of South America. For this event special missions and embassies representing 39 nations were sent to Lima, amongst whom were Gen. Pershing representing the United States and President Saavedra representing Bolivia.

The year 1925 was free from political disturbances, and during it President Leguía worked to bring to completion his far-reaching proposals for the reform of administration in Peru. The difficulties in his path were great and progress was slow, for, because of his virtual dictatorship, he had alienated the sympathies of many of the ruling class, which had hitherto regarded the privilege of government as reserved to its own members. The commercial community and the mass of the people largely approved of his methods, for many solid achievements stand to the credit of his régime: yellow fever has been stamped out, sanitation schemes have been initiated, construc-

tion and road-making have progressed, order has been, on the whole, successfully maintained, and the national finances, if not fully restored to equilibrium, have been greatly improved.

During the period 1910-25 the boundary dispute with Chile regarding the provinces of Tacna-Arica has at times, especially during the period 1922-5, overshadowed all other questions of home and foreign policy (*see* TACNA-ARICA).

*Defence.*—Military service is compulsory but not universally enforced, and consists of two years in the active army, five years in the first reserve, five in the second, and 20 years in the national guard. The peace establishment is 8,000 officers and men forming 13 regiments of infantry, seven of cavalry, and four of mountain artillery, together with units of coast defence and field artillery. There is a military school, a staff school, an engineering school and a military aviation school. Gendarmerie and police, including civil guards, have a personnel of 8,000. The army is modelled on that of the French Army and a French Military Mission was employed by the Government for instructional purposes. The navy in 1925 consisted of two light cruisers, one auxiliary cruiser, one destroyer, two submarines, and a river flotilla on the Amazon of six small units. There is a school for naval aviation. A North American naval mission has trained the personnel since 1920 and advised the Minister of Marine on technical subjects. The personnel of the navy was 179 officers and 1,500 ratings in 1925.

*Education.*—Primary education is compulsory, and free in the Government schools; secondary education is given in high schools at a moderate charge. In 1925 there were over 2,000 primary schools with 200,000 pupils. Each departmental capital has a high school supported by the Government with some 5,000 pupils. There are four universities—San Marcos at Lima; Arequipa, Cuzco, and Trujillo; there is also a school of mining and civil engineering.

## II. FINANCIAL AND ECONOMIC HISTORY

*Finance.*—The unit of currency is the Peruvian pound (£p.) equal at par to the £ sterling. Exchange from 1910 to 1916 was steady, but from 1916 onwards (owing to excess of exports over imports) the £p. was at a premium over the £ sterling, rising to 28½% in 1918 and to 30% in 1919. During the first half of 1920 it averaged 20%, declining to a discount of 14½% in 1921 but rising again to 16¼% premium in Jan. 1923, with slight variations up to Dec. 1925. Note issues amounted to £p.7,000,000 approximately, fully covered by gold. Public debt in 1923 amounted to £p.11,401,391 of which £p.4,371,049 was external. This was slightly increased in 1924 and 1925. The budget for 1914 was: revenue £p.3,547,836 and expenditure £p.3,709,836. For 1925 it was estimated to balance at £p.8,364,068. The principal sources of revenue are customs taxes on imports and exports, and taxes on miscellaneous articles.

*Production.*—Agricultural products in order of importance are:—sugar, cotton, wool, hides and skins. Other products are: castor oil, rice, hides, wheat, coffee, barley, lumber, potatoes, coca, cocaine and sisal hemp. Before the cultivation of plantation rubber after 1910, wild rubber, collected in the Peruvian Oriente, was one of the chief exports, but by 1925 the industry had practically ceased to exist; most of the interests formerly engaged in this industry are now devoted to cotton. With the exception of the Andean region, nearly the whole of Peru, and especially the valleys of the coastal region, is fertile. Considerable attention has been paid by the Government to irrigation. Before 1914 Peru imported wheat; in 1925 over 100,000 hectares were in cultivation, with an estimated production of about 75,000 metric tons. The area under sugar-cane approximates 1,000 square miles. Salaverry and Trujillo are the chief centres of the sugar industry, the annual production of sugar approaching 350,000 tons. Some 500 sq. m. are under cotton; mainly in the southern coastal areas: the annual production approximates 30,000 tons. Rice is extensively grown, some 30,000 tons being produced annually. Coffee is grown in the central areas: the cultivation of coca is extending. Coca is grown in the Cuzco, Ayacucho, and Huanuco districts: over 3,000 lb. of cocaine is exported

annually. Stockraising is of growing importance but is hampered by lack of sufficient labour; the alpaca, the llama and the vicuña are prized for their coats; but since 1920 a law has prohibited trade in articles made from vicuña wool. Mineral production is valued at over £10,000,000 annually, the chief minerals being petroleum, copper, silver and gold. The production of petroleum is increasing (see PETROLEUM). The coal output exceeds 300,000 tons per annum.

**Industry.**—Cotton spinning and the manufacture of sugar with its by-products are the chief industries. Apart from these two, Peruvian manufacturing activities are only of local importance, although there is much scope for development. The chief cotton-weaving factories are at Lima, Ica, Arequipa and Cuzco. There are altogether about 1,500 looms producing up to 25,000,000 yards of material annually, with an invested capital of over £p.500,000. Other manufacturing industries are: fuel, Panama hats, paper, woollen goods, fertilisers from guano, coca and by-products, and cotton by-products.

**Trade.**—After a decrease in trading caused by the outbreak of the World War, the European demand for Peruvian products brought a period of prosperity to the country, which continued with interruptions during 1920, 1921 and 1922 to 1925. In 1921 the Government organised a Trade Exhibition which was held in Lima.

The following tables give the value of the trade in £p. and the direction of trade during certain years:—

| Year              | Imports<br>£p. | Exports<br>£p. |
|-------------------|----------------|----------------|
| 1913              | 6,088,776      | 9,137,780      |
| 1920              | 18,358,224     | 35,304,155     |
| 1924              | 18,029,418     | 25,111,377     |
| 1925 <sup>1</sup> | 12,680,000     | 15,184,000     |

<sup>1</sup> First nine months.

Trade with Foreign Countries

| Year              | Great Britain |        | U.S.A. |        | Germany |        |
|-------------------|---------------|--------|--------|--------|---------|--------|
|                   | Exp. %        | Imp. % | Exp. % | Imp. % | Exp. %  | Imp. % |
| 1913              | 37.2          | 26.3   | 33.2   | 29.8   | 6.7     | 17.3   |

| 1924 <sup>1</sup> | 45.0          | 17.0   | 33.0   | 45.0   | 3.0     | 5.0    |

<sup>1</sup> Estimate.

**Communications.**—In 1914 there were 1,825 m. of railways, which had increased to approximately 2,030 by 1925. One-third of the railways of Peru are narrow gauge. The Peruvian Corporation, with registered offices in London and largely owned by foreign interests, controls over 80% of the railways, including the Central, one of the world's great achievements in railway engineering. This line of 248 m. runs from Lima to Oroya through the Andes, reaches a height of 15,665 ft. above sea level and serves important agricultural and mining districts. The Cerro de Pasco Railway is a branch extension of the Central, reaches a height of 14,300 ft. above sea level, and has a branch serving the coal-mining district of Goyllarisquica.

Roads are of little importance—although some 5,000 m. exist they are mainly tracks, only about 375 m. being suitable for motor traffic in 1925, but a further 300 km. were under construction or being planned. In 1916 the Government put forward an elaborate scheme of road construction which was yet uncompleted in 1925. Civil aviation was still in its infancy in 1925, although a school had been established at Lima and tentative efforts had been made in 1920 and 1921 for the establishment of air services along the coast. There are some 7,000 m. of navigable rivers, of which the chief is the Amazon with the Peruvian port Iquitos about 2,000 m. from the Brazilian port of Para, and visited by vessels of 2,000 tons. By an agreement made in 1921 the Marconi Wireless Telegraph Company took over the administration of the telegraphic and postal services. In 1925 there were 10,000 km. of telegraphs with about 350 offices. There were 664 post offices in 1911 and over 800 in 1925. The Peruvian Mercantile Marine consisted in 1925 of 12

steamers, 16 sailing ships and 80 small craft, representing 23,000 tons aggregate; the Compañía Peruana de Vapores, of which the Government owns one-half of the capital, is the only national steamship line.

**Banking.**—The principal bank is the Banco del Perú y Londres, which has its head office in Lima and has branches in the chief towns. In 1922 the Banco de Reserva del Perú, a central reserve bank, commenced operations and was granted the sole right to issue notes. A law passed in 1923 enacts that a branch of a foreign bank must have in Peru a capital of £p.200,000 and must have its obligations guaranteed. Deposits in banks in 1925 were estimated at over £p.12,000,000. The Government claims 6% of interest accruing on all current accounts.

Stationery Office, London. (P. A. ME.)

**PÉTAİN, HENRI PHILIPPE BENONI OMER JOSEPH** (1856–), French soldier, was born May 24 1856 at Cauchy la Tour (Pas de Calais). He was commissioned from St. Cyr 1878, passed in due course through the École de Guerre, filled various staff appointments, including that of instructor at the École de Guerre, and was promoted colonel in 1910. At the outbreak of the World War he was commanding an infantry regiment, but he was immediately given a brigade and then a division, and acquitted himself so well during the opening weeks of the struggle that he was advanced to the command of the XXXIII. Army Corps in Artois on Oct. 25 1914. He greatly distinguished himself on the occasion of the French offensive near Arras in May 1915, where his corps completely broke through the German position, though exploitation proved to be impossible for want of reserves.

On June 21 1915 he was given command of the II. Army, which under his orders carried out on Sept. 25 1915 the great attack in Champagne. After this action Gen. Pétaïn wrote a remarkable *Rapport sur les opérations de la IIe. armée en Champagne et enseignements à en tirer*. This contained the principles of a new tactical doctrine, and was published in the *Archives de la Grande Guerre*, No. 10, pp. 5–30.

After the battle of Champagne, the staff of the II. Army was withdrawn from the front, and was thus available at the moment when the Germans were attacking Verdun on Feb. 21 1916. It was then that the task of stopping the advance of the Crown Prince was entrusted to Pétaïn. On Feb. 24 he was summoned by telegram to general headquarters at Chantilly. From thence he proceeded immediately to his new headquarters, arriving there on the evening of the 25th. His chauffeur missed his way in the snow and Pétaïn himself was seized with pneumonia. No one knew this, however, but his doctor, and ill as he was he directed the battle during the first few days.

His first task was to organise the battle zone. He fixed a line of defence from Bras to Douaumont: this line had to be held at all costs, and under cover of it he divided up the ground to be held in sections which were duly laid out and equipped. It was largely owing to the system and energy of Pétaïn that Verdun was saved. On May 1 1916 he was given the command of the centre army group, of which the IV. Army, on the left, took part in the great offensive of April 16 1917. At the War Council held on April 6 at Compiègne, Pétaïn, while admitting that there was an opportunity for an offensive, had asked that it might be limited to definite objectives; but after the check on April 16 he was strongly opposed to its being continued. On April 28 he was appointed chief of the general staff at the Ministry of War in Paris; and on May 15 he replaced Gen. Nivelle as Commander-in-Chief of the armies in the field.

The French Army at that time was faced with a grave crisis, not excluding mutinies. Pétaïn did his utmost to remove the special causes of discontent, such as the irregularity of leave, and the inequality between units in their tours of duty in the trenches.

He also saw to it that soldiers on leave were not exposed to dangerous influences or neglect, and he renewed the confidence between the combatants and their leaders. He visited personally every division and questioned the officers. By means of reforms rather than measures of repression, he succeeded from the month of June onwards in having the army completely in hand. He saw clearly that, in view of the wastage in man-power caused by three years of devastating war, an offensive project on a great scale, such as his predecessor had adventured, was impossible for the time being. He therefore decided to exercise patience. In *directive* No. 1 he informed the army group and army commanders that they must limit themselves provisionally to preparing attacks with only limited objectives with the object of wearing out the enemy reserves. In *directive* No. 2, which was issued in the second fortnight of June, he reconstructed the training of the troops. In *directive* No. 3, at the beginning of July, he laid down the method of distribution in depth.

The keynote of the limited operations outlined by his *directive* No. 1 was to be thoroughness of organisation and the high proportion of fire-power, so as to give the maximum result with the minimum risk. Such were the characteristics of the action of the I. Army in Flanders, July 15-31; the II. Army before Verdun, Aug. 13-25; and of the VI. Army at Malmaison, Oct. 17-26.

Late in 1917 it became apparent that owing to the defection of Russia a formidable German offensive would be launched in the spring of 1918 on the Western Front. With this in view, Pétain studied the possibilities of surprise by placing reserves within reach of the threatened points. On Feb. 22 1918 he and Sir Douglas Haig agreed to give each other mutual assistance. Each commander-in-chief undertook in the event of the other being attacked to relieve a sector of his front in order to free a certain number of his divisions. This agreement was drawn up in document No. 5476.

On March 21 when the Germans had just attacked Gen. Gough's Army with great violence, Pétain hurried forward the V. Corps which was in reserve behind his left wing. On the 22nd Haig having requested the intervention of the French Army, Pétain pushed forward the extreme left or 125th Div. of the VI. Army towards the field of battle, where it arrived during the night March 22-3. Other French units were speedily added in order to assist the British, and these formed successively the III. Army and then the I.

Meanwhile, on March 26 at Doullens, Gen. Foch had been entrusted with the mission of co-ordinating the efforts of the Allied armies. Pétain therefore had only to carry out on the lines of the *directives* issued by Foch those operations which had been assigned to the French armies. He withstood the German attacks of May 27, June 9 and July 15, and as a tactical counter to the enemy's offensives, he planned in a note of June 24 new tactics of elastic defence under which the second line trench system became the main position of resistance.

It was now the moment to pass to the counter-offensive. On June 27 Foch had asked Pétain to draw up a *directive* for an offensive. This was the *directive* No. 5, July 1. The operation itself as originally planned was to consist of a move by Gen. Mangin's Army on Soissons. On June 14 Foch had ordered preparations to be made for an offensive against this town. On June 16 Pétain issued the same order to Gen. Fayolle, the commander of the army group. On June 20 Mangin, who was entrusted with its execution, drew up the plan of action, which consisted of preliminary operations which were to be followed by the occupation of the heights in front of the town. This plan was approved on June 27 and the first phase was carried out between June 28 and July 3. The preliminary successes led Mangin to think that the action could be further developed. On July 7 Pétain and Foch discussed this point; and next day Pétain sent Fayolle a letter in which he expressed approval of Mangin's plans. But on July 9 Foch conceived the idea of an action on a larger scale in which two other armies should take part. With this end in view Pétain on July 12 issued to the army group commanders instructions which were approved by Foch on July 13. On July 14 Foch went to see Pétain, and an agreement was

reached between them as to the time when the offensive should be launched. This was planned for the 18th. From these details it will be realised how close was the collaboration between the different sections of the command.

Pétain, under similar conditions, prepared the great offensives of Aug. 8 and Sept. 25 1918 and he was also responsible for pushing the Germans back to the Ardennes. On Nov. 21 Pétain received at the hands of the President of the Republic at Metz the baton of *Maréchal de France*; he was also the recipient of many high honours from the Allied Governments. He subsequently held the position of vice-president of the *Conseil Supérieur de la Guerre*; and it was in this capacity that he went to Morocco in the summer of 1925 to supervise the arrival and employment of the reinforcements which were sent out to carry on the campaign against Abdel Krim. (H. Br.\*)

**PETER I.** (1844-1921), first King of the Serbs, Croats and Slovenes, was the eldest son of Alexander Karadjorgjević, who had been elected as Prince of Serbia on the expulsion of the Obrenović dynasty in 1842, and was therefore grandson of Kara George, the first leader of Serbian independence. His father lost his throne in 1858 and withdrew to Austria, where Peter grew to manhood. Accused of complicity in the plot against Prince Michael Obrenović (1868), Prince Alexander transferred himself with his family to Switzerland, and Peter made Geneva his headquarters for many years.

In 1870 he joined the French Army as a volunteer and served with distinction in the campaign against Germany. In 1876 he joined the Bosnian insurgents against Turkey and fought under the assumed name of Peter Mrkonjić, leaving behind him a legend which had its influence on the young revolutionaries of a later generation. In 1882 he, the exiled Pretender, and not the newly proclaimed King of Serbia, was invited to attend the coronation of Tsar Alexander III., who resented Milan's dependence upon Vienna; and it was very largely due to the Tsar's personal influence that in 1883 Peter married Zorka, daughter of Prince Nicholas of Montenegro. For a time he lived at Cetinje and his children were born there, but after his wife's death in 1890 he again lived in Geneva.

In 1903 shortly after the murder of King Alexander and Queen Draga by a military gang, Peter was unanimously elected King of Serbia and though he was gravely embarrassed at home by the political interference of the regicides, and abroad by the odious circumstances to which he owed his accession, he set himself steadily to work for constitutional government, his tact, self-effacement and liberal outlook forming a marked contrast to the attitude of Serbia's previous rulers and contributing to the rapid political consolidation which followed the upheaval of 1903. In June 1914 ill-health forced him to entrust Crown Prince Alexander with the regency, and condemned him to a passive rôle during the World War. But the simplicity of his life, his stirring proclamations to his soldiers and the visits which he paid to the trenches in a half crippled condition, did much to encourage Serbian resistance; and he shared the privations of the great retreat across Albania, lying in a litter which was sometimes carried by soldiers, sometimes propped in a bullock cart. After the War and his election as "King of the Serbs, Croats and Slovenes," he lived mainly in retirement at Topola and died on Aug. 16 1921. (R. W. S.-W.)

**PETERS, KARL** (1856-1918), German traveller (see 21.300), in Feb. 1918 published an autobiography, and died at Woltorf, Hanover, on Sept. 10 of the same year.

**PETROGRAD** or **LENINGRAD**, Russia (see 24.38), the former capital of the Russian Empire is now the capital of the province of Leningrad. The Govt. was removed to Moscow on March 9 1918. The name was changed from St. Petersburg to Petrograd on Sept. 1 1914 and to Leningrad on April 22 1920. The city is in a far worse condition even than Moscow since the removal of the official bodies, and is only a shadow of its former self. The people are in a state of extreme poverty. The population, 1,429,000 in 1905, was officially given as 926,732 in 1921 and 1,067,328 in 1923, but another authority, in 1925, gave it as barely 500,000. The streets are grass grown,

owing to the small amount of traffic and full of holes; many of the houses are in ruins, and few shops or factories are open.

In Sept. 1924 there were disastrous floods, said to be the worst in the past century, when many bridges and quays were broken. The university, the custom house, the zoological gardens, one of the electrical stations and the central aqueduct were damaged. A number of books were destroyed in the library of the former Imperial Academy of Sciences, but many pictures and antiquities had been removed to museums in other cities, particularly from the Hermitage and Yusupov palaces. The palace of the Grand Duchess Xenia, which had been made into a naval museum, library and private dwellings, was destroyed by fire in 1924. In 1925 the roof collapsed over two halls of the Winter Palace. Institutes for the study of a number of branches of science have been established since the revolution, and in 1925 it was decided to erect an observatory on the dome of St. Isaacs Cathedral. It was stated early in 1926 that 364 churches, having been nationalised, were closed and dismantled of bells and other fittings; the procedure of the authorities being to fix a rental for the buildings beyond the means of the congregations.

Petrograd is the only Baltic harbour left to Russia, and is its chief port for imports, but much of the trade comes through Reval, Riga and Libau, which are strong competitors. The port is said by the Soviet authorities to have been re-equipped, and to have been up to pre-War standard in 1925, with a total length of quays of 21,000 feet. It is stated to possess the largest ice-breakers in the world for keeping a channel open when the port is closed by ice.

**PETROLEUM** (*see* 21.316).—Increased consumption and many new uses for petroleum products continuing to stimulate

FIG. 1.—The total world production of petroleum in 1924 was about two and a half times that of 1913. These diagrams show the percentage of the total produced by each of the chief producing countries in 1913 and 1924.

the search for petroleum in the older producing countries and in new territories, often remote from civilisation, has been rewarded by important extensions and discoveries, with the result that between the years 1908 and 1924 the world's annual petroleum production nearly quadrupled. This development was largely due to the increased production in the United States.

### I. THE PRODUCTION OF PETROLEUM

The following table from the U.S. Geological Survey gives the annual world's production from 1908 to 1924:—

*Barrels of 42 U.S. Gal.*

|                |             |                             |               |
|----------------|-------------|-----------------------------|---------------|
| 1908 . . . . . | 285,552,746 | 1917 . . . . .              | 508,687,302   |
| 1909 . . . . . | 298,616,405 | 1918 . . . . .              | 514,729,354   |
| 1910 . . . . . | 327,937,629 | 1919 . . . . .              | 544,885,000   |
| 1911 . . . . . | 344,174,355 | 1920 . . . . .              | 695,281,000   |
| 1912 . . . . . | 352,446,598 | 1921 . . . . .              | 765,928,000   |
| 1913 . . . . . | 383,547,399 | 1922 . . . . .              | 858,715,000   |
| 1914 . . . . . | 403,745,652 | 1923 . . . . .              | 1,018,900,000 |
| 1915 . . . . . | 427,740,129 | 1924 <sup>1</sup> . . . . . | 1,005,915,000 |
| 1916 . . . . . | 459,411,737 |                             |               |

<sup>1</sup> Estimated by *Oil & Gas Journal*, Tulsa, Okla.

Between 1908 and 1925 many prolific fields in the United States were developed, enabling that country to keep its pre-eminent position. Mexico, which rose from unimportance to second position during the period of the World War, retained that ranking among oil-producing countries during the post-War period, although total production declined. After 1908, Argentina, Colombia, Venezuela, Trinidad, Egypt and Persia developed production of commercial importance, Russia added the Maikop and Ural-Caspian fields, and Japan the Akita prefecture.

The production of the various countries in 1923 and 1924 is shown in the following table:—

| Country                     | 1923 <sup>1</sup><br>Barrels | % of<br>Total | 1924 <sup>2</sup><br>Barrels | % of<br>Total |
|-----------------------------|------------------------------|---------------|------------------------------|---------------|
| United States . . . . .     | 732,407,000                  | 71.9          | 717,000,000                  | 71.2          |
| Mexico . . . . .            | 149,585,000                  | 14.7          | 140,000,000                  | 13.9          |
| Russia . . . . .            | 39,156,000                   | 3.9           | 44,000,000                   | 4.4           |
| Persia . . . . .            | 28,793,000                   | 2.8           | 32,000,000                   | 3.2           |

<sup>1</sup> U.S. Geological Survey.

<sup>2</sup> Preliminary, *Oil & Gas Journal*.

### NORTH AMERICA

**United States.**—Petroleum production in the United States in 1924 totalled 707,265,000 bar. (net preliminary estimate U.S. geological survey). The following table, from the survey, gives the production of the important divisions in 1908, 1923–4 in barrels of 42 U.S. gallons:—

| District                            | 1908                 | 1923        | 1924        |
|-------------------------------------|----------------------|-------------|-------------|
| Appalachian . . . . .               | 24,946,000           | 28,225,000  | 27,049,000  |
| Lima-Indiana . . . . .              | 10,032,000           | 2,404,000   | 2,288,000   |
| Illinois and S.W. Indiana . . . . . | 33,686,000           | 9,500,000   | 8,732,000   |
| Mid-Continent . . . . .             | 48,834,000           | 348,460,000 | 368,729,000 |
| Gulf Coast . . . . .                | 15,772,000           | 33,271,000  | 27,642,000  |
| Rocky Mountain . . . . .            | 412,000 <sup>1</sup> | 47,653,000  | 42,761,000  |
| California . . . . .                | 44,855,000           | 262,876,000 | 230,064,000 |
|                                     | 178,537,000          | 732,389,000 | 707,265,000 |

<sup>1</sup> Including "others."

The Appalachian area includes Kentucky, West Virginia, Pennsylvania, New York and eastern Ohio. Oil and gas sands occur throughout a long stratigraphic interval, including rocks ranging in age from Ordovician to Carboniferous. Petroleum from this area is a high-grade paraffin oil, the average gravity being about 45° Baumé (0.8000 sp. gr.). The Lima-Indiana field covers northwestern Ohio and northeastern Indiana, the oil being obtained from lenses or discontinuous layers in Trenton limestone. The average gravity is about 39° Baumé (0.8285 sp. gr.), although some of the oil is much heavier. The principal productive area in the Illinois field is in the southeastern part of the State, but there are also scattered pools in central and western Illinois. Most of the oil is obtained from beds of sandstone in the Pennsylvanian and Mississippian series of the Carboniferous system. In gravity the oils range from 27° to 37° Baumé (0.8917 to 0.8383 sp. gr.).

The greatest increases in production between 1908 and 1924 occurred in the mid-continent field, embracing Oklahoma, Kansas, northern, central, eastern and southwestern Texas, northern Louisiana and southern Arkansas. Pools are scattered throughout the area and new pools are constantly being discovered. Most of the oil is obtained from sandstone or other porous rocks of the Cretaceous and Tertiary systems. The average oil has a gravity of about 35° Baumé (0.8485 sp. gr.), ranging from the thick black oil of some of the Louisiana and Arkansas fields, of 21° Baumé (0.9272 sp. gr.) or under, to the high grade Cushing oil of above 55° Baumé (0.7568 sp. gr.). The Glenn pool discovery in Creek county, Okla., in 1907 led to a great petroleum development in that State, the pool reaching a maximum production of 125,000 bar. a day. In 1912 the Cushing pool, also in Creek county, was discovered; the maximum production reached was 320,000 bar. a day, sustained for a 60-day period in 1914, and resulting in the collapse of the oil markets. In 1914 the Augusta pool in Butler county, Kan., was opened up, and in 1915 the El Dorado pool, also in Butler county; with the Towanda extension, the latter pool made over 100,000 bar. for a few days in Sept. 1917.

Late in 1917 the discovery of oil in a well 3,450 ft. deep near Ranger, in central Texas, resulted in a most sensational development, covering the widest "boom" area in the history of petroleum in the United States up to that time. The Ranger boom is significant in two main respects: it began a long series of great "wildcat" enterprises, the testing out of great areas of unproven oil lands, the results of which were still felt throughout the next decade; and it was the beginning of the movement on the part of American oil operators to drill deeper and deeper for possible oil sands, which was responsible for great volumes of the new production that has been developed. The Ranger development opened up extension pools in Eastland county, Stephens county, and adjoining counties. In July 1918 a prolific well opened up the Burkburnett pool development in northern Texas. Another important development in the mid-continent field was the discovery in Sept. 1918 of oil in a shallow well near Homer, in northern Louisiana: a large gusher at greater depth was brought in in Aug. 1919.

One of the most important developments of the early part of 1921 was the discovery of oil in commercial quantity in southern Arkansas. The El Dorado pool in Union county resulted. The Mexia pool in Limestone county, Tex., was developed in 1921. The "flush" production pendulum swung back to Oklahoma later in 1921, and in 1922 important extensions and discoveries resulting from deeper drilling occurred, the output of the state being chiefly increased by such pools as the Burbank, Bristow, Hewitt, Lyons-Quinn and Tonkawa. But the greatest succession of flush pools reaching their peak in the mid-continent field in conjunction with similar pools in California was in 1923, when Burbank and Tonkawa in Oklahoma, the original Smackover development in Arkansas, and the Powell field in eastern Texas, all in the mid-continent area, attained high production levels. In 1924 Oklahoma's bonanza pools showed little loss in production, Burbank was extended, and a prolific deep sand development occurred in the Tonkawa field. The Smackover pool in Arkansas was extended and production greatly increased. The sensational and short-lived Wortham pool in eastern Texas came in Dec. 1924. Several smaller pools, which in combination resulted in considerable new production, also came in during 1924 in Oklahoma.

The Gulf-coast field first came into prominence in 1901, when the Spindletop pool in Jefferson county, Tex., was developed. This field includes southern Texas and southern Louisiana, and the petroleum is associated with masses of rock salt and gypsum in domes. The age of the oil-bearing strata ranges from Cretaceous to Quaternary. The field includes a great number of small scattered pools, some of which have developed wells of enormous productivity. The gravity of the oil ranges from 15° to 30° Baumé (0.9655 to 0.8750 sp. gr.). Among the more important pools are the Goose Creek, Hull, Humble, West Columbia and Damon Mound pools. The Rocky Mountain

field, which embraces the areas of production in Colorado, Wyoming and Montana, as well as new producing and prospective territory in Utah, Arizona and New Mexico, was being tested by the oil driller in 1925 with good results; the greatest development was in the Salt Creek field of Natrona county, Wyoming.

The most sensational developments were in California, where oil production during the five years preceding 1922 had been running from 100,000,000 to 115,000,000 bar. annually. Before 1923 the principal producing districts were Kern river, McKittrick, Midway-Sunset, Lost Hills and Belridge in Kern county; the Coalinga field in Fresno county; the Lompoc and Santa Maria fields in Santa Barbara county; the Ventura and Newall fields in Ventura county; and the Los Angeles and Salt Lake and Whittier-Fullerton fields in Los Angeles county. The bulk of the production was heavy oil averaging about 21° Baumé (0.9272 sp. gr.). Important addition to production in the Midway-Sunset field was made in 1920-1 by the development of the Elk Hills district. But the most important discoveries were in 1920 of the Huntington Beach field, and in 1921 of the Santa Fé Springs and Long Beach fields, all in the Los Angeles basin. These fields reached their greatest production in 1923, and yielded high-grade, gasoline-bearing crude oil.

The production in barrels of the major pools in 1923-4 is shown in the following table, taken from "World Production of Petroleum in 1924" by E. de Golyer, *Transactions of American Institute of Mining and Metallurgical Engineers*:—

| Field            | 1923        | 1924        |
|------------------|-------------|-------------|
| California:      |             |             |
| Huntington Beach | 34,355,000  | 17,533,000  |
| Long Beach       | 68,810,000  | 60,122,000  |
| Santa Fé Springs | 79,781,000  | 26,309,000  |
| Total            | 182,946,000 | 103,964,000 |
| Wyoming:         |             |             |
| Salt Creek       | 33,645,000  | 30,879,000  |
| Oklahoma:        |             |             |
| Burbank          | 33,821,000  | 30,805,000  |
| Tonkawa          | 27,033,000  | 22,413,000  |
| Total            | 60,854,000  | 53,218,000  |
| Arkansas:        |             |             |
| Smackover        | 35,041,000  | 42,000,000  |
| Texas:           |             |             |
| Powell           | 32,243,000  | 33,374,000  |
| Total            | 344,729,000 | 263,435,000 |

By the end of 1924 California's three great pools had declined in production or showed signs of considerable decline, but considerable production was added in the Los Angeles basin district by the Torrance, Dominiquez and Rosecrans pools, and early in 1925 by the Inglewood pool.

*Alaska.*—Oil has been found in several localities in Alaska, notably in the Katalla field: in the Kayak field, several miles inland from Cape Suckling; in the Cook Inlet field, between Itimma Peak and Iliamna Lake; and in the Cold Bay field, opposite Kodiak Islands. Wells were drilled in the early 'nineties in the Kayak, Cook Inlet, and Cold Bay regions, but oil was not found in commercial quantity. Desultory search for oil in Alaska has continued. In 1923 the Associated Oil Co. and the Standard Oil Co. (California) drilled wells in the Cold Bay field without any favourable results being reported.

*Canada.*—Canada's production has declined since 1908. The output in 1924 was estimated at 175,000 bar., compared with 528,000 bar. in 1908. Virtually all of Canada's petroleum is produced in Ontario, and occurs in sandstone and limestone of Silurian and Devonian age. A small production is obtained in New Brunswick and Alberta. In 1920 oil was discovered on the Mackenzie river, 150 m. south of the Arctic Circle in the Canadian North-west Territory. The well was located northwest of Fort Norman, and on Aug. 23 1920 it began to flow over the

top of the mast from a depth of 783 ft.; after an uninterrupted flow of 40 min. the well was capped. In 1922 the well was deepened to 951 ft., with the result that a flow of 60 to 70 bar. per day was secured; it was again deepened in 1923 and the flow was increased to about 100 bar. a day. Two other wells were drilled in 1923 with negative results. During the summer of 1924 another well, 150 ft. east of the discovery well, was started and carried down to 975 ft., with an oil showing at that depth, and the test is being continued. In the autumn of 1922 oil was struck at Wainwright, 120 m. southeast of Edmonton, in Alberta. This has stimulated drilling in the Wainwright-Irma district. In 1924 a well producing oil of 73° Baumé was brought in in the Turner Valley field, 45 m. southwest of Calgary. It blew itself in on Oct. 14 and is stated to have produced at the rate of 400 bar. daily, with production steadily increasing.

**Mexico.**—Mexico's petroleum development, sensational in its rapid growth, has been, when considered from the view-point of individual wells and leases, equally sensational in its rapid decline. Mexico still ranked second among the world's producing countries in 1925, but its "golden lane" of the so-called southern field or Tampico-Tuxpam region, which supplied the bulk of the oil in the years 1919 to 1922 inclusive, has virtually been exhausted except for "stripping" operations. However, the northern or Panuco fields have done much to offset these losses. An interesting feature of the change that has occurred in Mexican petroleum relates to the fact that in the southern area the oil is so-called "light" oil, ranging from 15° to 29° Baumé (0.9655 to 0.8805 sp. gr.), while in the northern area the oil is "heavy," ranging from 10° to 14° Baumé (1.000 to 0.9722 sp. gr.). Thus the losses in production have been in the more valuable light oil. Mexican production in 1924 is estimated at 140,000,000 bar., which compares with 149,585,000 bar. in 1923 and 182,266,000 bar. in 1922. The change in the volume of light and heavy oil from 1922 to 1924 is shown in the following table:—

| Year | Light Barrels | Heavy Barrels | Total Barrels |
|------|---------------|---------------|---------------|
| 1922 | 136,503,000   | 45,761,000    | 182,266,000   |
| 1923 | 61,043,000    | 88,542,000    | 149,585,000   |
| 1924 | 35,500,000    | 104,500,000   | 140,000,000   |

Although yielding oil as early as 1901, it was not until 1910 that production of Mexico became a commercial factor. In the latter part of that year the Juan Casiano No. 7 well was drilled south of the Dos Bocas well, the latter an uncontrolled gusher south of Tampico, struck July 4 1908, which went to salt water several months later. The Potrero del Llano No. 4 well came in Dec. 27 1910, with an estimated initial flow of 10,000 bar. daily, increasing to 160,000 bar. and establishing itself as the largest producer up to that time. Both the Casiano and del Llano wells were in the so-called southern field as distinguished from the northern or Panuco field, these two fields being part of the Tampico-Tuxpam region. This lies in the northern part of the State of Vera Cruz and the southern part of the State of Tamaulipas. Oil in the Tampico region occurs in the Oligocene, Eocene, and Cretaceous formations, and is found in numerous pools. Before striking the big wells mentioned a considerable production had been developed at Ebano, 40 m. west of Tampico, in the northern part of the Tampico-Tuxpam area and in the Tehuantepec area. The Tehuantepec-Tabasco area extends along the Gulf coast in southern Vera Cruz and the State of Tabasco. Its oil-bearing rocks are of the Pliocene and Pleistocene age, and it had not developed a large production up to 1925. Oil in the Tehuantepec field has a gravity of 32° Baumé (0.8642 specific gravity).

#### CENTRAL AND SOUTH AMERICA

No petroleum production has been developed in Central America, but prospecting has been done and some drilling was under way in 1924-5. Test wells have been sunk on Columbus Island, off the east coast of Panama, and in the Estrella valley of Costa Rica. Exploration work has been done in Honduras and Guatemala.

**Argentina.**—Argentina's commercial production dates from 1908. Late in 1907 petroleum was found in a well being drilled for water by the government near Comodoro Rivadavia, Chubut province, on the coast of Patagonia. The government immediately reserved part of the oil-bearing land, and Argentina's petroleum development has thus been in large part in the hands of the government, although in recent years private companies have been active both on government lands and on privately held lands. Argentina's oil production is estimated at 4,000,000 bar. in 1924, compared with 3,400,000 bar. in 1923, and slightly over 1,000,000 bar. in 1919. Innumerable indications of oil, asphalt, rafaelite, etc., occur throughout the whole length of the country. Heavy oil is found seeping out near Punta Arenas on the Straits of Magellan, in the beds assigned to the Tertiary period, but no systematic prospecting operations have been carried out. The most southerly wells are drilled in the neighbourhood of Santa Cruz, but the results recorded are of a discouraging order. From Comodoro Rivadavia the oil belt extends northward through the territory of Neuquen and the provinces of Mendoza Salta and Jujuy, to the Bolivian border, a distance of about 1,500 m., the width being unknown. Broadly, the oil-bearing formations exploited belong to the Cretaceous at Comodoro Rivadavia, the Upper Jurassic in the province of Neuquen, the Triassic (Rhaetic) at Mendoza, and range from Upper Mesozoic to the Devonian in Jujuy and Salta. Most of the production since the beginning of operations in Argentina has come from the Comodoro Rivadavia field. The oil is heavy and of asphalt base, and ranges in gravity from 18.9 to 21.8° Baumé (0.940 to 0.922 sp. gr.). Argentina in recent years has seen great prospecting and development activity and has great potentialities.

**Venezuela.**—Active prospecting in Venezuela began in 1910, and during the next four or five years wells were drilled in several areas with varying success. A well in the Mene Grande field, on the east coast of Lake Maracaibo, Sucré district, drilled in 1913, established the occurrence of oil in paying quantity, and by 1915 the field had developed a considerable production, furnishing up to 1921 practically all the Venezuelan output. Drilling in the district of Colón, State of Zulia, commenced in 1914. Four wells credited as good producers in the Rio Oro and Rio Tarra sections had been completed by 1916 and were shut in. Two wells reported as proven in the Bolivar district, State of Zulia, were also capped. Operations in Venezuela in 1920-1 were active, particularly in the Lake Maracaibo district. During the period 1921-5 several important fields have been added to Venezuelan producing territory. In 1924 the estimated production was 8,200,000 bar., compared with 4,059,000 bar. in 1923. Commercial production in the Mene Grande field dates from 1917 and has steadily increased. The field is located about 75 m. southeast from the city of Maracaibo on the eastern side of Lake Maracaibo and about 12 m. from the shore. The oil is a heavy oil.

In the La Rosa field, located on the east side of the lake about 27 m. southeast of the city of Maracaibo, the first drilling was done in 1915, but after the completion of two small wells operations were virtually discontinued until 1922, when the La Rosa gusher, which produced over 1,000,000 bar. in nine days before it sanded up, was brought in. Competitive producing with many wells drilled in the lake adjacent to the shore has been a feature of the La Rosa development, which has recorded many large wells, practically all of which have experienced difficulties in sanding up and which, therefore, are being pinched down to reduce the pull on the sand. In 1925 La Rosa was the largest producing field in Venezuela. The oil is a heavy oil. Another field which has attained commercial production is El Mene, which is located in the northeastern semi-arid part of the Maracaibo basin and about 36 m. inland from the lake. The oil is a light oil, and the wells, which are comparatively shallow, are not of the large volume, gusher type. The La Paz and Concepción fields, about 15 m. apart, are located on the west side of the lake. Both fields have been proven and further drilling is in progress, while exploratory drilling throughout Venezuela is occurring.

**Colombia.**—Colombia is one of the recent arrivals in the oil-producing columns, and in 1924 was credited with an output of 600,000 bar., compared with 424,000 bar. in 1923. The principal development and the only one on a commercial scale is that of the Infantas field, on the De Mares concession, located on the Rio Colorado in Santander del Sur. The field is approximately 350 m. from the mouth of the Magdalena river. At the end of 1924 there were 17 producing wells in the field, some of them shut in. Preliminary work was started in 1925 for laying a pipe line from the field to the coast. Other test work with varying results has been carried on. Oil from the Infantas field is reported to test 26° to 31° Baumé (0.8974 to 0.8696 sp. gr.).

**Peru.**—Peru is the oldest oil-producing country in South America, first being credited with production in 1896. Its production has been steadily maintained, the principal fields being Negritos, Lobitoa and Zorritos. Another petroliferous district near Lake Titicaca has not developed any considerable production. Oil is found chiefly at the north (Pacific coastal district), and occurs in several horizons of soft sandstone and shale of early Tertiary age. The oil ranges from 32° to 48° Baumé (0.8642 to 0.7865 sp. gr.). Production has steadily increased, and in 1924 the output was credited at 7,500,000 bar., compared with 1,011,180 bar. in 1908. This does not represent maximum production, as much production was shut in during 1924 owing to the depression of the world's oil markets. The bulk of the

output comes from the Negritos field, which in 1924 produced approximately 6,500,000 barrels.

*Prospecting in Other States.*—Bolivia and Ecuador have been actively prospected, but oil in commercial quantity has not been developed. Chile has had several oil booms, particularly those based on the oil deposits of the province Punta Arenas, northwest of Tierra del Fuego, but without successful results. Prospecting has been undertaken in Brazil and Uruguay.

#### THE WEST INDIES

*Trinidad.*—The oil-fields of Trinidad are mainly in the southern part of the island, the oil being obtained from lenses of sandstone of Tertiary age. Trinidad first appeared as an oil producer in 1908, although in 1902 wells were known to exist north of the Pitch Lake at Guayaguayare, in the extreme southeast of the island. This district became prominent in 1908, when a well at 700 ft. spouted oil over the derrick, and a rapid development followed. Oil in the Pitch Lake district varies in density from 14° to 25° Baumé (0.9722 to 0.9032 sp. gr.). In the latter part of 1911 regular oil shipments from Brighton began. In that year several large gushers were brought in, but immediately clogged, owing to sand. In 1913 a well came in rated at 40,000 bar. daily, but sanded up, and in subsequent years other large producers have been reported, the initial production of which has soon fallen off on account of sand. Trinidad's production in 1924 totalled 3,750,000 bar., compared with 3,051,000 bar. in 1923.

*Cuba.*—An oil boom in Cuba in 1917 failed to yield any considerable production. The principal development was in a field near Havana. Prospecting and a little drilling work have been done in Santo Domingo and exploration work carried on in Barbados and in Haiti.

#### EUROPE

*Russia.*—While Russia, as a result of the World War and the revolution that followed, dropped in world rank as regards petroleum production, it remained the largest European producer. Oil is found in Tertiary clays and sands. Baku oils are of about 27° Baumé (0.8917 sp. gr.), while in the Suraghany district of Baku province the oil is as high as 48° Baumé (0.7865 sp. gr.). The relatively small area comprising the Baku field supplies the bulk of Russia's production. Other productive fields are the Grozny, Maikop, Ural-Caspian (Emba), and Cheleken fields. The Maikop field in the province of Kuban on the north flank of the Caucasus, northeast of the Black Sea, was discovered in 1910. Maikop oil is about 40° Baumé (0.8235 sp. gr.). The Ural-Caspian field, covering a large area in the Emba-Uralsk region round the north end of the Caspian Sea, first became a commercial factor in 1913. Emba oil is about 28° Baumé (0.8861 sp. gr.). For many years the island of Cheleken—off the Asiatic coast of the Caspian Sea near Krasnovodsk, was the scene of moderate operations, and from 1911 onwards large yields were obtained from wells sunk in the Ali Tepe district in the southwest. Cheleken oil is about 22° Baumé (0.9211 sp. gr.).

The Russian revolution disorganised the oil industry. Production was 72,801,110 bar. in 1916, but it had dropped to 25,429,600 bar. by 1920. In May 1921 the industry was nationalised and was then built up at a fairly steady rate to a production of about 44,000,000 barrels. Soviet officials reported that in the early part of 1925 production was attaining pre-War level.

*Galicia* (Poland).—Galician production showed a declining tendency after 1909, and during the World War the decline was aggravated, as the fields were battlegrounds. The largest output is obtained from Eocene beds. The chief producing areas are: in eastern Galicia, Boryslaw-Tustanowice, and Biłkôw; in western Galicia, Bobrka, Potok and the Gorlice district. The bulk of Galicia's production comes from the Boryslaw-Tustanowice district. Boryslaw oil is 32° to 34° Baumé (0.8642 to 0.8537 sp. gr.), and is the standard market grade for Galicia. Biłkôw oil is about 53° Baumé (0.7650 sp. gr.); Bobrka, about 31° Baumé (0.8696 sp. gr.), Potok, 34° to 45° Baumé (0.8537 to 0.8000 sp. gr.). Production in 1924 was approximately 6,000,000 bar.; the peak of production was in 1909 with 14,932,799 barrels.

*Rumania.*—Like Galicia, a battleground during the World War, Rumania suffered in petroleum production. Most of the oil is obtained from Miocene and Pliocene beds, but part is from Eocene and Oligocene and possibly from Cretaceous beds. The principal fields are Bûsténari, Campina, Moreni, Filipești, Bâicoi, and Buzău. The oil is from 25° to 45° Baumé (0.9032 to 0.8000 sp. gr.). Production in 1924 was 13,000,000 bar. and had practically reached the maximum output prevailing before the World War.

*Germany.*—Oil is obtained largely at Hanover, where it occurs in domes associated with rock salt. The rocks are chiefly limestone and sandstone of upper Jurassic age. Oil at shallow depths is heavy, gravity from 17° to 19° Baumé (0.9524 to 0.9396 sp. gr.); at greater depths the oil is lighter. The production is very small.

*France.*—Production in Alsace occurs in sandstone of Eocene and Oligocene age and is comparatively small. The gravity ranges from 25° to 29° Baumé (0.9032 to 0.8805 sp. gr.).

*Italy.*—Italy's production, relatively small, is chiefly in the Emilia district of Lombardy, on the northeastern slope of the Apennines. Oil occurs in sandstones of Eocene and Miocene age, and ranges from 31° to 48° Baumé (0.8696 to 0.8187 sp. gr.).

*Great Britain.*—Apart from the shale-oil industry of Scotland and Wales, Great Britain joined the list of petroleum-producing countries in 1919, when the Hardstoft well was brought in in Derbyshire. This was one of 11 drilling locations, seven of which were in Derbyshire, two in north Staffordshire and two in the Midlothian district of Scotland. The Hardstoft well was started in Oct. 1918 and struck oil in May 1919, at 3,078 feet. At 3,100 ft. it produced 10 or 11 bar. daily. The well was still overflowing naturally at the end of 1920. Up to that time its production totalled 4,575 bar., or 590 tons, of which 2,909 bar., or 375 tons, were produced in 1920. After 1920 production declined. Other test wells have failed to develop a commercial production. Oil from the Hardstoft well tested 40° Baumé (0.8236 sp. gr.).

A considerable production of petroleum is derived from the Scottish shale-oil fields stretching from Dalmeny and Abercorn on the Firth of Forth southward to the district of Cobbinshaw and Tarbrax. The oil-shale industry in Scotland has been in commercial operation since 1850; in 1917, 3,116,529 long tons of oil were produced. There is a small oil-shale production in England and Wales.

#### AFRICA

*Egypt.*—Prospecting in Egypt resulted in the discovery of oil on the borders of the Red Sea and the development of small production in 1911. In 1913 several large wells were brought in in the Gamsah district on the west shore of the Red Sea, near the junction of the Red Sea and the Gulf of Suez. In Oct. 1914 oil was struck in the Hurghada district, south of Gamsa, and up to 1925 Egypt's production had been mainly confined to these districts. The oil occurs in sandstone and in cavernous, dolomitic limestone, associated with thick beds of gypsum of Miocene (Tertiary) age, accompanied in some places by thick beds of salt. The underlying Nubian (Cretaceous) sandstone also contains some oil. Egyptian oil is about 40° Baumé (0.8235 sp. gr.). Difficulties from salt-water flooding have been encountered in the fields, shortening the life of the large wells. Exploitation has been restricted to a comparatively small area, but exploratory work has been carried on in other areas. While Egypt's production almost doubled in 1918 as a result of increased activities that year, it fell off in 1919, and in 1920 showed a sharp decrease. Production in 1918 was 2,079,750 bar.; in 1919, 1,501,000; and in 1920, 1,042,000. From 1920–5 production failed to increase.

*Other Areas.*—Some oil has been obtained in the Shelif river area in the district of Oran, Algeria. Over 30 wells have been drilled in the Msila and Mejila districts, but during the World War operations were practically discontinued. Interest in Algeria revived after the War. The oil-bearing formation is probably Upper Miocene and its structure is complex. Prospecting has been active in Angola and Ashanti, in the Tertiary coastal plain formations, and tests have been drilled in Angola in the Alto Daude district near Loanda and at Ambrizette. Showings of oil were reported in test wells drilled in the Betsiriry valley, Madagascar, but no commercial production developed.

#### ASIA

*Persia.*—Persia is looked on as a new petroleum-producing country of unusual importance. Development has been virtually confined to the Maidan-i-Naftun field in northern 'Arabistan, about 100 m. north of the head of the Persian Gulf, where the first wells were completed in 1908. In 1914, 10 wells were reported as being operated, and 20 more were shut down at the top of the sand. In the neighbouring Maidan-i-Naftek field one well had been drilled and capped and a second begun. One test well had started in the White Oil Springs district. The following year a total of 12 wells had been completed in the Maidan-i-Naftun field. The oil is rich in naphtha content. The entire Persian production up to 1925 was from flowing wells of the Maidan-i-Naftun and nearby pools, all controlled by the Anglo-Persian Oil Co., Ltd. In his report to the general meeting of the company in London on Nov. 25 1924, the chairman stated that production from the Persian fields was then at the rate of 4,500,000 tons (34,650,000 bar.) per year—the maximum quantity that they were then able to dispose of, and that much production was closed in. He further stated that the company's production could be brought up to 10,000,000 tons (77,000,000 bar.) per annum by opening all existing wells, and that it could be further augmented within a few months by drilling in wells that had been carried only to the cap rock. Well F7, in the Maidan-i-Naftun field, maintained a flow of over 11,000 bar. daily from its discovery in Nov. 1911, and is reported to have produced about 6,000,000 tons (46,200,000 bar.) up to 1925. In addition to the Maidan-i-Naftun field, the Ahwaz Pusht-i-Kuh, Qishm Island and the Persian Gulf regions are expected to yield petroleum.

*Iraq.*—There are several petroliferous areas in the Tigris-Euphrates basin. Primitive development has yielded some oil in the Kirkuk-Mandali-Qasr-i-Shirin area north of Baghdad, in the Middle Tigris belt and in the Euphrates belt. Large-scale development of the fields was interrupted by the War, but interest in them was revived during the post-War period.

*Palestine.*—The first drilling for oil in Palestine, southwest of the Dead Sea, was interrupted by the War. Prospecting had previously been active in the area between the river Jordan and Dera'a, adjacent to the Hejaz railway.

**India.**—The principal source in India is the Yenangyaung field in Burma, about 272 m. north of Rangoon on Yenangyaung creek. Other important districts are the Singu, Minbu, Pakokku and Upper Chindwin. The oil is in rocks of Miocene age and is about 30° Baumé (0.8750 sp. gr.). Deep drilling was a feature of the development in this field after 1914. Some wells came in with a large initial flow, but fell off rapidly owing to the intense development of the territory. Coal-bearing rocks of Eocene age have yielded oil in small quantities in Assam and in the Punjab. India's production in 1924 was estimated as 7,500,000 bar., representing a substantial decline from its peak year.

**Japan and Formosa.**—Japan's principal oil production is found in the Echigo province field. Since 1908 the most important development has been in Akita prefecture. The first gusher was drilled in this field in May 1914, flowing at the rate of 12,000 bar. daily. Many other large wells have been developed. The Akita gushers have declined rapidly. Oil is obtained from coarse sandstone layers, interstratified with sandy shale of Tertiary age. The oil is about 25° Baumé (0.9032 sp. gr.). A small production is also obtained in Formosa. Production of Japan and Formosa in 1924 was estimated as 1,500,000 bar., representing a substantial decline from the peak.

**China.**—A joint investigation of petroleum resources in the provinces of Shensi and Chihli was undertaken in 1914 by the Chinese Govt. and a private corporation. Drilling of six wells began in the Yenchang field, Shensi, where previously a number of primitive wells had been put down and a small production obtained. In 1916 the abandonment of the enterprise was announced. No oil in commercial quantity was struck.

#### OCEANIA AND THE EAST INDIES

**Dutch East Indies.**—Production of petroleum in the Dutch East Indies has shown a steadily increasing tendency. Production is obtained in Sumatra, Borneo and Java. Most of the oil-bearing rocks are associated with beds of coal and lignite of Miocene age. Oil of the Langkat district of Sumatra has a gravity of 33° to 55° Baumé (0.8589 to 0.7692 sp. gr.). Java oil is heavier, ranging between 23° and 40° Baumé (0.9150 to 0.8235 sp. gr.). Borneo oils from shallow wells have a gravity of about 14° Baumé (0.9722 sp. gr.), and from the deeper wells a gravity of from 27° to 33° Baumé (0.8917 to 0.8589 sp. gr.). Production of the Dutch East Indies, including a small production from British Borneo, was 10,500,000 bar. in 1924.

**Papua.**—Test drilling has been undertaken in Papua, and, while oil has been struck, difficulty has been caused by mud clogging.

**Philippine Islands.**—Prospecting and drilling work started in the Philippine Islands in 1920 in the Bondoc Peninsula district.

**Australasia.**—Extensive prospecting and drilling work have been done, especially in New Zealand in the vicinity of New Plymouth, in South Australia, in the Robe district, and in Queensland, in the Roma district. Exploitation in these districts has failed to develop petroleum production in commercial quantity. New South Wales has developed an oil-shale production amounting in 1922 to 32,489 tons, which, however, fell to 23,467 tons in 1923.

## II. GROWTH OF THE INDUSTRY

**Oil in the World War.**—Petroleum was of vital importance in industrial, military and naval operations during the World War. Industrial plants required abnormally large quantities of lubricating oils and fuel oils. There was a rapid growth in the numbers of oil-burning ships, and a new demand for petroleum was made by aircraft, by the introduction of petrol-burning motor-launches, by tanks used in military operations, and by the creation of the motor transport. In all the belligerent countries special departments were organised to handle petroleum problems, and drastic restriction of home consumption was enforced. The inter-Allied petroleum council, consisting of representatives of Great Britain, the United States, France and Italy, was formed in 1917, and arranged for the requirements of each of the Allies and for the transportation of the petroleum allotted. America supplied 80% of the Allied petroleum requirements. The transportation of these great quantities necessitated large additions to tanker fleets, particularly those of Great Britain and the United States. In 1918 there were 2,628,961 tons of fuel oil alone shipped from the eastern seaboard of the United States for the use of the Allied navies. In the same year more than 1,000,000 tons of distillates and other petroleum products also crossed the Atlantic, entailing more than 500 tank steamer loadings. War-needs also brought a realisation of the value of petroleum products, and extensive investigations into possible substitutes were made.

**Financial and Industrial Progress.**—The expansion of petroleum activity involved a great increase in financial requirements. While the tendency was towards consolidation and the

perfecting of large organisations, there was also, particularly in the United States, an extraordinary growth of smaller companies, some of them embracing all fields of petroleum enterprise. The Standard Oil and Royal Dutch-Shell groups are outstanding examples of world-wide petroleum operations, and the Anglo-Persian Oil Co., which originally confined its operations to Persia, expanded them to other fields to include all phases of petroleum activity. The original Standard Oil Trust, following prosecution under the Sherman anti-trust law, was broken up in 1911 into 33 companies, most of which were operating before as separate entities. Probably the most progressive of these companies, apart from the parent New Jersey company, is the Standard Oil Co. (Indiana) which in 1925 acquired a dominating interest in the Pan-American Petroleum and Transport Co., with principal producing properties in Mexico and with a distribution business for fuel oil and other products in many parts of the Western Hemisphere and in Europe.

In 1909 the approximate investment in the oil industry in the United States, tankage, refineries, pipe lines, tank cars, tank steamers and marketing equipment—was \$800,000,000. In Jan. 1926 it was nearly \$9,000,000,000, divided approximately into production \$4,500,000,000, refineries \$2,300,000,000, pipe lines \$700,000,000, tank cars \$270,000,000, marketing equipment \$800,000,000, and tank steamers \$430,000,000. Much of this expansion is attributable to the automobile, which has completely revolutionised the oil industry. In 1909 there were 311,000 automobiles registered in the United States; at the end of 1924 there were 17,600,000 depending upon the petroleum industry for gasoline and lubricating oil.

In 1924 the production of crude oil in the United States was 714,000,000 bar. and 78,000,000 bar. were imported, as against 128,000,000 bar. produced and an insignificant quantity imported in 1909. There were 357 refineries with a daily crude oil capacity of 2,481,000 bar. operating at the end of 1924, as against 147 refineries with a daily capacity of probably less than 500,000 bars. in 1909. The output in barrels of products by refineries in 1924 compared with 1909 was as follows:—

|                   | 1924        | 1909       |
|-------------------|-------------|------------|
| Gasolene          | 213,000,000 | 14,000,000 |
| Kerosene          | 60,000,000  | 46,000,000 |
| Gas and fuel oils | 320,000,000 | 40,000,000 |
| Lubricating oils  | 28,000,000  | 13,000,000 |

Note: Figures from U.S. Bureau of Mines.

The great increase in the use of gasoline was accompanied by an increase only slightly less momentous in the use of fuel oil. The navies of the Great Powers began to use fuel oil shortly before the War, which made the conversion from coal almost complete, and, further, brought about the use of oil by fast passenger and cargo vessels. On June 30 1925 world oil-burning vessels (including motor ships) of 500 gross tons and over totalled 3,822, aggregating 19,372,615 gross tons, compared with 501 ships, totalling only 1,721,747 tons, registered in 1914.<sup>1</sup> The growth of the motorship, or the internal combustion Diesel and semi-Diesel engined ship, requiring a petroleum fuel oil, was the most pronounced development in shipbuilding from 1923 to 1925. In the United States fuel oil is in fairly general use under boilers in industrial plants. A new and growing use is in household burners; many types of these, however, burn a kerosene distillate called furnace oil. In 1925 the approximate annual consumption of gas and fuel oil in the United States was: by railroads, 63,000,000 bar.; merchant vessels, 55,000,000 bar.; United States Navy, 6,000,000 bar.; electric plants, 17,000,000 bar.; gas manufacturing plants, 23,000,000 bar.; and industrial plants and homes, 128,000,000 barrels.

**Nationalisation.**—Nationalisation of oil-bearing lands, i.e., the retention or vesting of ownership of subsoil rights in the hands of the State, has been a pronounced tendency in certain countries. In Russia, petroleum lands were nationalised and are operated by the Soviet Government. Argentina's petroleum development has been almost entirely in the hands of the Government. In May 1917 a new Mexican constitution provided for the nationalisation of petroleum,

<sup>1</sup> Lloyd's Register and the U.S. Bureau of Navigation.

specifically Art. XXVII. and various decrees were promulgated in the attempts to carry out the nationalisation principle. Several efforts were made by the Mexican Congress to pass a petroleum code interpreting Art. XXVII., and in 1925, such a bill was passed by Congress. In other Latin-American countries nationalisation is generally adhered to in working out petroleum codes. Direct Government interest in petroleum development was brought about in Great Britain by the action of the British Govt. in becoming a majority shareholder in the Anglo-Persian Oil Company. Rumania in 1924 adopted and was putting into effect a new mining law which provided for the nationalisation of the oil industry.

Federal petroleum legislative activity in the United States has never gone so far as serious advocacy of nationalisation. In Feb. 1920 a general leasing bill was passed by Congress as a relief measure and as a means of practical handling of lands which had been withdrawn from public entry, including large naval oil reserves. In June 1920 there was further enactment giving the Secretary of the Navy powers covering leasing and operation of the naval reserves. In May 1921 a presidential decree authorised transfer of the administration of the naval reserves from the Secretary of the Navy to the Secretary of the Interior. The withdrawal of public lands was a conservation measure developed as part of President Roosevelt's broad conservation programme. Late in 1924 President Coolidge appointed a Federal Oil Conservation Board, comprising the secretaries of Interior, War, Navy and Commerce, to study the Government's responsibility with regard to the conservation of oil.

The American Petroleum Institute committee on conservation made an exhaustive study of the petroleum resources of the United States and of the future demand for petroleum, and rendered its report to the Federal Oil Conservation Board in Aug. 1925. The committee found no imminent danger of exhaustion of the petroleum resources of the United States.

### III. TECHNICAL DEVELOPMENTS

**Finding Oil.**—The principal advance in the geological technique of oil finding is along the line of improvement in subsurface correlation by means of foraminifer studies, additions to the knowledge of which are being made slowly but surely, and by means of mineral, and especially heavy mineral, determinations in well samples. The general application of geophysics by means of torsion balances and seismographs, has proven the greatest new aid to geology. The physicist has offered in these two types of instruments which will permit, under special conditions, the location of salt domes, faults and anticlines.

There are three types of torsion balances—Eotvos, Bamberger and Oertling—but all are essentially the same as the original Eotvos in principle, varying only in portability, sensitiveness and the presence or absence of a self-recording photographic attachment. These instruments give the differential in millionths of the density of adjacent portions of the earth's surface. Thus beds of a higher density below one part of the surface, as in the case of limestone-anhydrite capped salt domes, may be distinguished from those of lower density such as ordinary unconsolidated sediments, surrounding them. The seismograph attempts to make use of an entirely different principle—that of the differentiated velocities of pressure waves, refracted through different rock masses, such pressure waves being actuated by the explosion of a small charge of dynamite (one to two hundred pounds) at or slightly below the surface, and the recording of such waves, usually photographically, by means either of one of two general types of seismographs—mechanical and galvanometric.

**Drilling Systems.**—The principal drilling systems are: (1) percussion, which includes the standard cable tool (American system) and the pole tool (Canadian system); (2) hydraulic rotary system; (3) combination system; (4) hydraulic circulating system (see 21-319). Though differing in design and construction, the several drilling outfits have many features in common. Regardless of the method or system employed, the power plant generally consists of a portable boiler, capable of developing from 30 to 70 H.P. and a standard type of horizontal steam engine of from 20 to 50 horsepower. Well depths range from a few hundred feet to over 6,000 ft., the deepest producing wells being in California. Deeper drilling in the United States has accounted for much of the greatly increased production. A well of average depth in the mid-continent field could be drilled and equipped for less than \$13,000 in 1913. In 1915 the cost increased to about \$14,000; in 1918 to \$24,000; in 1920 to \$30,000 and in 1925 to about \$35,000 or \$40,000. In Mexico, where the wells usually have a great initial production and where the yield of individual wells is often restricted only because of inadequate marketing facilities or as a precaution against water inroads, the percentage of current production that might be termed "flush" is much higher than in any other producing country.

The Canadian pole tool system is used in Canada, while the deeper drilling in the Calgary district has been done by the standard cable system, and there has also been some rotary drilling. The standard cable system is principally used in Venezuela, although there has been a good deal of drilling with the rotary method and a combination of both. Wells in Colombia have been drilled by the cable system and combination cable and rotary. The standard cable system of drilling is generally used in Peru, but there has been some rotary drilling in the Zorritos field. Drilling in Argentina has been

largely done by the Galician pole tool system, which is a modification of the Canadian system, the equipment providing for a larger and heavier rig. The American standard cable system is also in use in Argentina, and there is some rotary and also hydraulic circulating drilling. In Trinidad, rotary drilling is employed almost exclusively for this purpose.

The free fall system, a modification of the Canadian pole tool system, is used in Russia. In this there is a free fall of the tools, which are then picked up; American methods are also being adopted. In Galicia, as well as in Rumania, the Canadian pole tool system, modified and adapted, is generally used, but the hydraulic circulating system is also in use. The standard cable system with portable rig is used almost exclusively in Italy, and the same system, without portable rig, in Persia, India and Egypt. The Galician pole tool system is used in the Dutch East Indies. In Japan the rotary system, introduced in the Akita field in 1913, is used almost exclusively. Electric power has made advances in the United States, in Texas, Wyoming, California and the mid-continent fields. It has been adopted in Rumania, and in the Balakhani-Sabunchi-Romani-Surakhani area and the Bibi-Eibat field of Russia. Electrification of the Yenangyaung field of Burma has also been undertaken. The use of compressed air to increase oil extraction has been introduced in certain producing areas.

**New Exploration Methods.**—In the mid-continent field of the United States, core drilling (either by the diamond drill or ordinary rotary method) has been employed to advantage. Improvements have been made in taking cores from wells. Up to 1925 no satisfactory device had been worked out which would enable an oriented core to be obtained. The use of cores for determining the amount of dip, even without an orientation, is of value in finding oil. Palaeontological examination of well cuttings will open up new sources of oil and much is being done on correlation by microscopic examinations. During the post-War period the most notable progress in the application of new methods was made in the Gulf Coast area of Texas and Louisiana, where the salt dome type structure governs oil accumulation. Geophysical methods have been applied with notable success. The discovery of three domes by means of the torsion balance and the seismograph is the first result of exploration by geophysical methods. Great possibilities exist of recovering from depleted oil fields. In 1925 four methods of oil recovery from depleted oil fields were in use: flooding, air or gas pressure, dewatering and mining. All these methods have been successfully used, the first three in the United States and the fourth in France. The most notable achievements in flooding are in the Bradford (Pennsylvania) field. Under the auspices of the American Petroleum Institute a movement to standardise oil-well equipment had gained great headway by 1925 and was being closely watched in other countries. Committees were working on the standardisation of specifications for steel and iron pipe, rig irons, wire rope and manila cordage, rigs and derricks, cable drilling tool joints, pumping equipment and engines, rotary drilling equipment, belting, oil-field boilers and steel storage.

### IV. TRANSPORT AND STORAGE

**Pipe Lines.**—With its large crude oil production obtained from fields often far from refining and consuming centres, the petroleum industry of the United States has developed pipe line systems of great mileage and capacity (see 21-320). In the fields themselves there are networks of gathering lines connecting the wells with main trunk lines and railways; the trunk line systems connect the fields with the refining centres. It was estimated in 1924 that the length of pipe lines in the United States amounted to about 65,000 miles. Practically all of the crude oil produced is transported by pipe line, some of it only a few miles and some of it as far as 1,700 miles. Pipe lines in Mexico have been constructed from the Panuco and Topila fields to Tampico and from the southern fields to Tampico and directly from the southern fields to the Gulf coast, where sea loading lines are installed. There is an international trunk line running into Canada connecting with lines in Ohio. Pipe lines are part of oil development in all countries, usually connecting oil fields with refineries or with railroads or sea terminals.

**Sea Loading Lines.**—Sea loading lines have been installed and are operating in Mexico, Peru, Trinidad, Russia, California and other places. These lines make possible the loading of vessels several miles at sea and are usually installed where no deep water harbours exist and where, because of the shallow water, the building of piers would be very expensive. The lines are submarine and are usually coupled ashore, stretched out on rails, and drawn into the water by vessels. When it is impossible to couple the pipe ashore, this is usually done on barges or rafts and the line deposited as the work proceeds. The sea loading lines off Tuxpan, Mexico, have been pulled up following failure of Mexico's "golden lane."

**Storage.**—Crude oil storage facilities, steel tanks or reservoirs, are grouped together on what are generally known as tank farms. Steel tanks are usually of 37,000 or 55,000 bar. capacity, placed about 500 ft. apart from centre to centre. Each tank is surrounded by a levee of sufficient height to hold the entire content of the tank, and enclosed for the purpose of isolating fires. Crude oil is stored in steel tanks, concrete tanks and earthen reservoirs, while many of the lease tanks are wooden. In the United States, at the end of 1924, 348,000,000 bar. of crude oil were held in pipe line and tank farm

storage. Tanks are installed at refineries for holding oil during the running at the plants and for storage preparatory to shipment to markets. Stocks of refined products held at United States refineries at the close of 1924 totalled 114,000,000 barrels. Investigation and experimentation are constantly directed to the reduction of evaporation losses of crude oil and refined products during storage. Tanks are usually protected from fire by steam lines from the boiler house so that free steam can be turned into the tanks on the approach of a thunder storm. This steam displaces the explosive mixture in the tanks. The water spray method is also used. At pipe line stations, and at tank farms and refineries where there is a large number of tanks, fire protective systems which utilise a frothy or foam mixture are often installed.

**Tank Vessels.**—The tank vessel plays a large part in the modern petroleum industry. It is used for transporting crude oil from producing countries and districts to refining countries and centres, and for carrying refined products in bulk to the markets of the world. On June 30 1914 world tankers numbered 366 vessels, totalling 1,441,196 tons; on June 30 1925 the world's tankers of 500 gross tons and over numbered 1,072, with aggregate tonnage of 5,310,533 tons, of which 478 vessels, totalling 2,411,719 tons, were American and 352 vessels, of 1,936,132 tons, were British. Great advances have been made in tanker construction and in loading and unloading cargoes.

## V. THE REFINING OF OIL

**Refinery Operations.**—The rapid expansion of the internal combustion engine, which, as developed in motor vehicles, began to be of importance as a consuming agency of petroleum products in 1907, caused gasoline (petrol) to become the chief by-product of crude oil. Later, the conversion of coal-burning vessels and industrial plants to the use of oil, and the extension of utilisation of the Diesel engine (an internal combustion engine which does not demand so volatile an oil as gasoline) in the marine and in the industrial fields, placed fuel oil in a position of great prominence. Even so great an increase in crude oil production as was recorded between 1908 and 1924 could not have supplied these consuming agencies had not refining methods been improved, new processes developed, and refinery capacity greatly expanded. As in the case of crude oil production the greatest refinery expansion has been in the United States. It is estimated that in 1915 there were 302 refineries with a crude oil capacity of 1,043,245 bar. daily; on Nov. 1 1924 there were 553 refineries with a daily capacity of 2,934,842 barrels.

United States refineries in 1924 ran 644,000,000 bar. of crude oil and produced 8,960,000,000 gal. of gasoline, 2,521,000,000 gal. of kerosene, 13,460,000,000 gal. of gas oil and fuel oil, 1,155,000,000 gal. of lubricating oil, 516,000,000 lb. of wax, 761,000 tons of coke and 2,546,000 tons of asphalt. The principal refining centres in the United States are in the mid-continent territory, in the Pennsylvania region, and along the Atlantic, Gulf and Pacific coasts. Every large producing area has developed, a refining industry, while the seaboard plants, in most instances, owe their location to strategic advantages respecting large domestic and export markets. Mexico has built up a substantial refining industry, although the largest proportion of its crude oil production is transported to the United States for topping and refining, in most part by Atlantic and Gulf coast plants. Most of the Mexican plants are topping plants (that is, they divide the crude into tops, distillates and gas and fuel oils) but there are a few more complete refineries. All the refineries are located along or adjacent to the Gulf of Mexico or the eastern seaboard, comparatively near the producing fields.

Canada has developed a substantial refining industry, these refineries operating on Canadian, United States, Mexican and Peruvian crude oil. There are one or more refineries or topping plants in Venezuela, the island of Curacao, Colombia, Trinidad, Peru and Argentina, these operating on domestic oil or oil imported from nearby territories. Galician crude oil is handled by refineries located within a radius of about 150 m. from the city of Lemberg, in and near the oilfields, and also by the continental refineries in Hungary, Austria and Germany. It is estimated that Galician refineries are capable of handling about 40 % of the crude production. Rumania's refineries are mainly located in the Prahova district and also in the Bacău, Dâmbovița, Constanța and Neam districts. Russian refineries are located at Blacktown, a suburb of Baku, and at Grozni, Bolshaya, Rakushka, Ekaterinodar and Shirvansky. There are local refineries at Suez in Egypt, and in Persia, India, the East Indies and Japan; Persian oil is also being handled by a refinery at Swansea, Great Britain.

**Refining Methods.**—The processes employed in the separation of the various constituents of crude petroleum into marketable products are many and varied, and while often apparently complex in nature, can be ultimately resolved into one or more of the basic methods listed below, or else fall under the head of allied operations, such as blending, compounding, grease-making, distilling, etc. These latter are not strictly refining processes in a purely technical sense, but are all incidental to the general operation of a refinery. Basic refining methods are: fractional distillation, chemical treatment, cold pressing, fractional fusion, cold settling, decolourisation and cracking. Fractional distillation, distilling or, "stillling" as it is often termed, may be defined as the separation by volatilisation of one group of petroleum constituents from another, in some form of closed appara-

tus, by the aid of directly or indirectly applied heat. Except in the case of a few unimportant crudes, it is universally practised and is the most important art in the whole scope of refining. Distilling methods may be classified under distillation by dry heat; (a) topping, skimming and stripping, (b) coking, (c) rerunning, (d) sweetening, (e) cracking; and distillation by steam; (a) steam stilling, (b) reducing, (c) cracking.

The adoption of continuous process stills was one of the most important advances, occurring about 1910. They were first introduced by Norman Henderson, a British chemist in connection with the distillation of shale oil. This system was subsequently universally adopted. Topping and skimming plants to raise the flash point and to dehydrate heavy oil multiplied rapidly, particularly in the United States. Numerous special refining processes have been introduced, and it is practicable to give only a partial list representative of types; the simplex refining (Trumbull) process, originally intended as a continuous topping system, has been so improved that it is now a highly efficient method for the fractionation of almost any type of crude; the Sharples process of centrifuging is another; the Edeleanu process brings out the possibilities of the separation of petroleum products by selective solvent action; a purely chemical process is that of Carleton Ellis, American chemist, for the production of Petrohol (isopropyl alcohol); more recently Dr. A. D. Little, American chemist, announced the development of secondary alcohol recovery processes.

In 1926 the petroleum industry was in the midst of intensive development of distillation methods, the most important phase of the business. Evidences of this are the bubble tower, thermal efficiency and high vacuum. Twenty years before, the early recognition of the value of heat exchange resulted in the use of a shallow tank or box in the ground filled with water and containing submerged pipes through which the ingoing cold oil and the rundown hot oil were circulated separately. From this exceedingly indirect beginning has come the highly developed heat exchanger with its compact arrangement and high-speed efficiency. Various types of drums and pots on the overhead lines from stills, particularly for the redistillation of light products, were the forerunners of the bubble towers and dephlegmating columns which serve their purpose in a more complete separation of desired products in a single or limited number of operations.

Scientific development along the line of chemical treatment has resulted in several new methods, such as the hydrochlorite process for the conditioning of light distillates, the process for the use of liquid sulphur dioxide, and various phases of the use of anhydrous aluminium chloride. Several extraction methods for reducing emulsions and obtaining more or less valuable by-products have also been proposed. Sulphuric acid and soda still remain the chief reagents for treating processes. Development of continuous counter-flow methods, which have been of particular advantage in the handling of light products, is an engineering contribution to the advancement of the art of treating petroleum products. The old cumbersome method of removal of wax from petroleum products has been superseded by modern pressing equipment. The refiner now has at his disposal almost any range desired of artificially low temperature. One of the most convincing developments along this line has been that of the centrifugal method for the removal of wax in the production of bright stock, which has been utilised by the engineer in the conservation of crude oil supply; thousands of barrels of cut oil are now being conditioned to pipe line grade by this comparatively simple means. As regards filtration or decolorisation, Fuller's earth is the chief agency used for decolorising and purifying mineral oils; its use has been developed mainly along the line of recovery processes which serve to put the clay into a condition for re-use more or less approximating the fresh material. Some special furnaces have been developed for this purpose. More attention has recently been given to the use of finer grades of earth, which has resulted in the development of the so-called contact process. The application of this process consists primarily of the mixing or contacting of the fine adsorbent at much higher oil temperature than had been used for percolation. Claims are made for further gains in colour yield, as well as quality, when the oil to be contacted has received a light preliminary acid treatment with or without neutralisation. At the same time, considerable attention is being given to the improvement of adsorptive materials themselves, with the result that there are a number of high-powered clays on the market which give excellent results when properly applied.

**Cracking Processes.**—The growing importance of the internal combustion engine made necessary a higher yield of motor fuel from the limited crude oil supply, if the demands of this consuming agency were to be met. The progress that was made after 1913 in the cracking art represents the greatest scientific achievement of the oil industry between 1910 and 1925. Cracking has made possible the supplying of a sufficient quantity of gasoline to meet the tremendously increased demands of the motor car, as evidenced by the estimate that in 1924 cracked gasoline amounted to over 20 % of the total gasoline manufactured at American refineries. The basic feature of all gasoline cracking is the subjecting of a hydrocarbon (such as gas oil) to superatmospheric pressures and high temperatures, which accomplish the breaking up or cracking of the molecules of the stock under treatment. The residue from one treatment by a crack-

ing process may be again and again subjected to the same process until substantially the entire mass is converted into gasoline. The percentage of gasoline which it is possible to extract from a given quantity of crude oil depends largely upon the quality of the oil. Cracked gasoline in general appearance is indistinguishable from first run or straight run gasoline and is not kept separate in handling or shipping.

Cracking processes may be classified into two groups: (1) processes in which the oil in vapour form is thermally or energetically treated (2) processes in which the heat or other form of energy is applied to the oil in liquid form, with some part of the liquid in contact with the vapour. The use of pressure or of catalysts may be a part of processes of either class (see 21.322). Actual commercial development dates from the patents of Dr. W. M. Burton, American chemist, in 1913. Dr. Burton's processes, controlled by the Standard Oil Co. (Indiana), were widely installed throughout the industry under licensing arrangements from 1917 to 1921. More recently the use of other processes have greatly increased. Probably the best known of modern successful cracking systems are the Burton, including the modifications of Humphreys, Clark and others; Ellis tube-and-tank; Cross; Dubbs; Holmes-Manley; and Jenkins; but there are many others employed by individual companies which are not so widely known because they have never been offered for licensing to other companies.

**Natural Gas.**—The United States and Canada produce all but a small fraction of the natural gas output of the world (see 21.321). The main areas of Pennsylvania, West Virginia and Ohio have developed remarkable staying qualities, and these three States produced some two-thirds of the total production of the Continent. The mid-continent field has shown a great increase in the natural gas production, and the Wyoming field has proved productive. There is some natural gas production in Russia, Rumania, Persia, Galicia, India, Japan and Mexico. The total production of natural gas in the United States in 1924 was 1,016,000,000,000 cu. feet. It is estimated that no less than 14,000,000 inhabitants of the United States use this fuel as a source of heat, light and power.

**Natural Gasoline.**—Natural gasoline, sometimes termed natural gas gasoline, or casing-head gasoline, has grown into a large industry and scientifically has made great strides. Although the foundation of the natural gas gasoline industry in the United States was laid in 1903-4, the real expansion of this important phase of gasoline production began in 1909. In 1911, the first year for which the statistics on the subject are available, 132 plants produced 7,425,839 gal. of raw gasoline from natural gas. In 1924 the industry included 1,096 plants, which produced 933,861,000 gal. of raw gasoline. Of the total, 639 were compression plants producing 257,894,000 gal., 445 were absorption plants producing 670,678,000 gal., and 12 were charcoal plants producing 4,064,000 gallons. In 1925 the methods of extracting gasoline from natural gas depended upon the principles of compression, cooling and absorption. The use of gasoline stabilising processes for minimising losses occasioned by evaporation and weathering of natural gasoline, has far-reaching influences upon the properties of products as obtained from the various extraction processes.

**Marketing of Products.**—Expansion of the use of petroleum products has resulted in many improvements in marketing methods and great additions to marketing equipment and facilities. In the United States a large number of tank cars is used in transporting products from refineries to consuming centres and to ports for shipment. The tank car is still used to some extent to carry crude oil from the field to refineries, chiefly when a new field is opened up and before pipe line connections have been made. Tank cars are widely used in Europe for petroleum products. There were 49,901 petroleum tank cars in the United States and Canada on Jan. 1 1914, and by 1924 the number had increased to 125,862. Rigid requirements are enforced in tank car construction in the United States. Cars must be of steam boiler quality, and exceptional strength is prescribed for the frame. The insulated tank car to handle highly volatile casing-head gasoline has been successfully introduced, and is also being adopted for transporting straight-run gasoline because it reduces loss by evaporation. The growth of motor vehicle gasoline demand, particularly extensive and rapid in the United States, has created new distributing methods and devices.

Fuel-oil bunkering stations have been established along the ocean routes to meet the increase in the oil-burning naval and merchant fleets of all countries. These stations include large storage tanks, and in some cases, berth and loading facilities, but in many instances they are simply storage reservoirs and oil is loaded on steamers from barges supplied from these stations. It is estimated that the number of fuel-oil stations for steamships located on trading routes approaches 300.

**PETROLOGY** (see 21.323).—Since 1910 there has been a steady advance in all departments of petrology. For many years the description of the microscopic characters of minerals and rocks was held to be, if not the only, at least the most important, part of petrographical literature. Text-books of petrography were in general a description of the recognised rock types, their composition, structure and the stages of their decay, with notes on their geographical distribution and their geological age. Chemical analyses were used principally as a means of identifying the classes to which individual rocks belonged and as a guide to the minerals of which the rocks consisted.

More attention of late years has been directed to other problems connected with rocks—such as the conditions of their origin, their chemical classification and the physical laws which determine what minerals shall be formed, in what order they will crystallise and through what stages they will pass when subjected to cooling, pressure and metamorphism. There is no difficulty now in attaining temperatures such as occur in the deeper parts of the earth's crust and in the interior of volcanoes and in maintaining these temperatures quite steady for several days or weeks if necessary. The electric pyrometer has reached such precision that an error of one or two degrees is all that need be expected in measuring temperatures up to 1600° Centigrade. Very high pressures can be easily obtained provided the temperature is low and there is no necessity to study the action of compressed gases. It is less easy, however, to perform experiments by which the action of steam and other gases on molten rock magmas at temperatures about 1000° and under pressures over 100 atmospheres can be exactly determined. More than one investigator has now been able to attain this, and a very correct reproduction of the conditions under which igneous rocks crystallise is consequently possible in the laboratory.

Descriptive petrology has been by no means in abeyance though the five years of war turned the activities of many geologists to other fields. Exploring expeditions, such as those of Scott, Shackleton and Bruce in the Antarctic, have brought home large collections of rocks which have been examined and described, and the constant activities of geological surveys in all parts of the world, together with the researches of geological specialists, have added largely to our knowledge.

**Igneous Magmas.**—Of the three great groups into which rocks are naturally subdivided, the sedimentary, igneous and metamorphic, the first is on the whole best understood and presents the smallest number of unsolved difficulties. The manner in which sediments are laid down on the bottoms of seas and lakes, in river deltas and valleys and on land surfaces, at the present time is open to investigation by simple means, and, except in the case of the deposits of the deeper parts of the oceans, is reasonably clear. Igneous magmas, on the other hand, are essentially obscure in their origin and history, and they have been the subject of much investigation in recent years. The origin of magmas is a problem belonging to geology rather than petrology. They have been regarded as unconsolidated remnants of the primeval molten globe, which by geological changes, such as the secular contraction arising from cooling and the pressures by which mountain chains have been upheaved, have

been afforded an outlet to the surface, where they appear as volcanoes, or have been forced between the rocks of the upper layers of the earth's crust, where they may be laid bare by subsequent denudation as "bosses" of granite or gabbro or intrusive sills of porphyry or dolerite. Others have held that magmas may arise in whole or in part by the fusion of solid rocks (of any of the above three classes); the agencies producing fusion being rise of temperature, either through crushing and movement or by depression into those regions where a high temperature naturally prevails, or through penetration of gases from the earth's interior which are not only intensely hot but are capable of combining and setting free large quantities of energy. It is conceivable also that deep within the earth's crust masses of rock occur at temperatures so high that, if pressure be relieved by the vaulting-up of the overlying crust or by fissures opening to the surface, they may become liquid and rise through any available channels.

Hardly less obscure than the origin of magmas is the question of their variety or differentiation. The outstanding fact in this connection is that no large developments of igneous rock are really homogeneous, and even in small masses a great number of varieties or rock-species occur frequently, differing in their chemical composition and their minerals. Granite, diorite, gabbro, norite and peridotite may all occur within a small outcrop not more than one or two square miles in area. The origin of differentiation has been much discussed. Some have ascribed it to diffusion or to a principle by which the heavier atoms in the molten mass will be concentrated either towards the bottom or towards the cooler edges or surfaces of contact with the surrounding rocks. Along these lines no satisfactory explanation has been found. More recent speculations have followed three lines: (a) subsidence or flotation of crystals; (b) absorption of sedimentary or other foreign rocks; (c) concentration of vapours.

(a) *Subsidence or Flotation of Crystals.*—When crystals form in a liquid they will, if heavier than the liquid, tend to subside and be collected near the base; and if lighter, they will tend to rise. If the crystals differ in composition from the liquid, as they usually do, consolidation will result in a mass which is not homogeneous. Thus, for example, olivine crystallises early in a basic magma and, being heavy, will tend to sink; consequently magnesia and iron will be in excess (and silica will be less abundant) at the base; while feldspar will predominate towards the top of such a mass. Instances occur showing this arrangement, but they are very exceptional; it is not the case that dolerite and gabbro masses as a rule have a pale-coloured felspathic top and a dark base rich in olivine and the oxides of iron. For such cases as do occur another explanation is often available. If now it were possible at an advanced stage in crystallisation to drain away or force into another position the still liquid part of the magma a type of rock different from the original magma would be produced, because most of the heavy ferromagnesian minerals would have been abstracted.

(b) *Absorption of Foreign Rocks.*—A second method of differentiation which has received much attention of recent years is by absorption of country rock. A gabbro mass, for example, may be supposed to dissolve a felspathic sandstone with which it is in contact and thus give rise to a more acid magma which might be represented by quartz-dolerite or even by granite. Intrusive masses of igneous rock, as they ascend from beneath, break across the overlying strata and may shatter them into many small blocks. On these and on the surrounding walls a solvent action is likely to take place. If the invaded rock is heavier than the intrusive magma its fragments will tend to sink, and as they are warmed up they will slowly disappear. There can be no doubt that this action is by no means unusual, and many good instances of it are known, but there is little reason to believe that it is an important cause of differentiation. Where igneous rocks have absorbed sediment in any quantity they present in general an abnormal facies. Granites, for example, which have dissolved clay, slate or mica-schist usually contain andalusite, sillimanite, cordierite, garnet or corundum, minerals which do not normally occur in such rocks. The magmas are said to be "contaminated." Gabbros under similar conditions contain cordierite, garnet and an excess of hypersthene (forming cordierite norites) and are easily distinguished from normal gabbros. Absorption of limestone by some nepheline syenites is indicated by the presence of crystalline calcite in the igneous rock, and peridotites may contain corundum. Perhaps the diamond is an accessory of this type in olivine rocks which have dissolved graphitic matter. Even when igneous rocks are absorbed the result will as a rule be an abnormality. This is fairly evident in the majority of cases merely by a study of the analyses of true igneous rock-types and ordinary sediments.

(c) *Concentration of Vapours.*—The theory that differentiation of magmas arises from the formation of partial magmas during cooling,

which separated because they became insoluble in one another (as phenol does with water), is favoured by many geologists, but an examination of the physical laws determining the production of such magmas has led to the conclusion that nothing is known that would make this process appear likely. Many geologists, however, who have a wide knowledge of igneous rocks in the field, hold that there is evidence to show that differentiation took place before crystallisation began, and that the various types of rock were already distinct when they were injected in liquid form into the positions they now occupy.

It has been suggested, though it has not been clearly explained, that the gases dissolved in magmas determine the sequence of crystallisation and may exert a powerful influence in differentiation. A magma rich in gases when it begins to crystallise yields crystals of anhydrous minerals. The gases, if they do not escape, must increase in relative amount in the liquid residuum. The early minerals are those like olivine and augite, which can be crystallised without difficulty from anhydrous melts; the later minerals, such as the alkali feldspars and quartz, crystallise readily only in presence of steam and other gases (or of solvents of a nature not usually present in rocks). In some respects the crystallisation of an igneous rock resembles the cooling and evaporation of a saline solution, the gases playing the part of solvent. The minerals appear in the order of their insolubility. It is probable that the history of magmas will never be clearly understood till a very careful study is made of the consolidation of rock-making silicates under high pressures of steam and other gases such as are known to abound in natural volcanic magmas.

*Classification of Magmas.*—The igneous rocks of one geological period and province have often so many peculiarities in common that they can be regarded as having resulted from the consolidation of a single reservoir of molten matter. The chain of volcanoes that fringes the shores of the Pacific Ocean from Tierra del Fuego to Alaska, and thence by Japan and the Philippines to Java and Sumatra, is characterised by rocks which have so much similarity in many important characters that they are certainly of allied origin, even if they have not proceeded from the one source. These rocks are all of Tertiary and recent age; their eruptions began in Eocene or Miocene time and have continued, with more or less frequent intermissions, up to the present day. For another example of this we may take the igneous rocks of the western and mid-Atlantic area, from Jan Mayen, through Iceland, the Hebrides, Canaries, Cape Verde Islands, etc.

All these volcanic centres have many rock types in common, and the whole assemblage is strikingly different from the Pacific igneous rocks. Each of these magmas has been taken as a type, and it has been found that in the older geological periods they are also represented; for example, the early Devonian eruptions in Scotland are distinctly of the Pacific type, while the carboniferous eruptions in the same district are of the Atlantic type. If we seek for a precise definition of their respective characters, it is not easy to give a complete answer. It may be said, however, that the Pacific suite has a great prevalence of hypersthene andesites, and andesites of all kinds. The Atlantic lavas, on the other hand, are predominantly olivine basalts, with trachytes and phonolites. Another feature which is especially striking is that practically all the rocks carrying nepheline and other felspathoids or "alkali minerals" are found in the Atlantic suites. This has been regarded as proving that the Atlantic magmas are richer in alkalis and the Pacific in lime, but it is by no means certain that this is the explanation. In fact, a full chemical discussion of the relations of these rock-series to one another has yet to be undertaken, but from the work of Becke it seems that the Pacific are essentially richer in silica, and in the "light" elements generally, while the Atlantic contain more of the "heavy" elements, such as magnesia, iron, chromium, titanium.

Several authors have pointed out that the rocks of the Pacific group are associated with a folded mountain chain, and consequently have appeared in a region undergoing lateral compression and upheaval; the Atlantic, on the other hand, are associated with a region of subsidence, with vertical dislocations along lines of fissure and faulting—in other words, a region subjected to lateral tension and depression. A third group of igneous rocks, very well characterised and distinct in many respects, is the pillow lavas or spilites, which are perhaps the most abundant volcanic rocks of the earlier geological periods and are very widespread in the Lake Superior district, middle Europe, Wales and Scotland. Among these lavas types rich in soda are common

and albitisation is a frequent pneumatolytic change. These rocks seem to accompany depressions formed in consequence of folding.

**Experiments on Constitution of Binary Magmas.**—A molten rock magma may be regarded as a liquid composed principally of oxides (mostly silicates). It crystallises from a variety of causes, of which cooling is the most important, though relief of pressure and escape of gases may also play a part.

The laws followed in such a case have been very carefully investigated, not only for metals, salts and organic compounds but also for many minerals. It is generally true that a mixture of two substances will have a lower consolidation point than either of the pure substances. Thus salt and ice, if mixed in the solid state at temperatures a little below the freezing-point of water, will melt, forming a liquid which is colder than the ice originally taken; and aqueous solutions of salts have always a freezing-point lower than that of pure water. For each pair of substances there is a definite mixture which has the lowest temperature of consolidation, and this is known as the *eutectic mixture*.

In the diagram (fig. 1) the horizontal co-ordinate represents composition, the vertical represents temperature. A mixture of any given composition is represented by a vertical line, and different points in that line represent different temperatures of the mixture. The two sloping lines AE and EB divide the diagram into two regions, of which the uppermost indicates substances in a purely liquid state; below the line the substance is in part or wholly in a solid condition. A vertical (composition) line, accordingly, when it cuts these lines shows where a substance begins to crystallise. The point where the curves meet is the

FIG. 1.

eutectic point E, and shows the composition of the mixture which has the lowest freezing temperature, and the temperature at which it consolidates.

The horizontal line drawn through the eutectic point separates the diagram into two regions, a lower one in which the substance is entirely solid and an upper one in which liquid is present. If we take any vertical line in the diagram, it will indicate a mixture of definite composition ST and, followed downwards, it shows the changes taking place in such a mixture as the temperature falls. Above the line AE the mixture is a cooling liquid. At S crystallisation begins. At T the last liquid portion disappears and consolidation is complete; below T the substance is a cooling solid. The diagram refers only to substances that crystallise on solidifying; glasses are solids which essentially resemble highly viscous liquids in their properties. When crystallisation begins the substance which is in excess of the eutectic mixture will crystallise out first, the residual liquid becoming poorer in that component until it has reached the eutectic composition, when the two components will go on crystallising simultaneously till all is solid. The composition of the liquid will travel along the line AE from S to the point E, where it will remain constant.

Such a diagram is based on a series of experiments in which a known mixture of two substances (very carefully purified) is heated in a furnace (generally electric) to a temperature well above its melting-

FIG. 2.

point. The mixture is then allowed to cool slowly and steadily, and its temperature recorded at short intervals or continuously by some form of pyrometer or recording thermometer. The rate of cooling can be very accurately ascertained and plotted (fig. 2). Crystallisation is attended by liberation of heat (the liquid losing its latent heat as it passes into a solid), and this involves a retardation of cooling. The simple liquid cools at a uniform rate; crystallisation begins and the cooling slows down; at a certain point the liquid is all

crystallised and the mixture, now a solid mass of crystals, will go on cooling uniformly. The change of slope in the curve of cooling accordingly corresponds to the passage of the substance from S to E in temperature (or from the purely liquid to the purely solid areas).

The physical condition of the substance at any given temperature can also be ascertained by the method of chilling. If the charge be taken from the furnace and plunged in water (or in some cases mercury) the mixture consolidates almost immediately, and any parts which were liquid will assume the form of a glass, or a very finely crystalline aggregate. This is especially the case with silicates, many of which crystallise with difficulty. Microscopic investigations will enable us to determine the nature and relative proportions of the crystals which were present. The results obtained can be checked by experiments on mixtures having a different composition, and in this way a complete diagram built up on a sound experimental basis.

The case outlined above is the simplest known. Many complications may appear, requiring special precautions and elaborate investigation. Thus the liquid may not begin to crystallise at the proper point on the upper curve, as some substances crystallise with difficulty and the liquid becomes "undercooled." A heating-up experiment may be tried to check the cooling experiments; the same phenomena should appear in the reverse order if no complications are present. Many silicates crystallise with great difficulty in ordinary crucible experiments (such as the feldspars, albite and orthoclase). Again, it may be impossible to melt the mixture we desire to investigate in any furnace which is suitable for experiments of this kind. Magnesia, alumina and lime are examples of substances which cannot be fused at temperatures such as 1600° to 1700° C., which are the limits of accurate work in our laboratories at present; part of the diagram accordingly will be incomplete when substances like these are studied, but an approximate solution can generally be made by extrapolation. Another frequent complication is the appearance of transformations in the solid state. The first mineral to crystallise becomes unstable as the temperature falls and changes spontaneously into another crystalline form of the same substance. The change will be attended by an alteration in the slope of the cooling curve, for in such cases heat is either liberated or absorbed, and successful chilling tests can often be made by which the mineral transformation can be clearly demonstrated. Silica, for example, appears in three minerals, cristobalite, tridymite and quartz, the transition temperatures being 1470° and 870°.

Each of these minerals occurs in two forms. Below 1190° calcium metasilicate crystallises as wollastonite; above that temperature it forms another mineral, pseudo-wollastonite. Many of these "high-temperature" forms are not known as natural minerals, and as a rule they are very rare in rocks, probably because rock cooling is essentially a slow process, and the most stable forms at low temperatures are the only ones likely to be present when the mass has completely cooled. Some very interesting results have been obtained in this field of research; for example, it is known that quartz has two modifications, one above 575°, the other below that temperature, and it has been proposed to use quartz as a geological thermometer and to show at what temperature it crystallised in a rock mass. If above 575° it would appear as one kind of quartz and on cooling would pass into another; and by various indications, such as crystalline form, cracks, etc., a record of this transformation may be obtained.

Very interesting modifications of the process of crystallisation occur when two or more of the minerals formed are members of an isomorphous series and can in consequence form mixed crystals. This is very common among the minerals of igneous rocks, of which the feldspars, pyroxenes, olivine (and probably also hornblende, mica, nepheline and the feldspathoids) all belong to isomorphous series. If we have, for example, two components such as albite and anorthite, they will tend to form mixed crystals (known generally as plagioclase feldspars). Anorthite has the higher melting-point (about 1550° C.); albite crystallises in crucibles only with great reluctance at a temperature about 1100° Centigrade. A mixture containing equal proportions of anorthite and albite will melt at about 1450°, and on cooling will begin to form crystals at that temperature. These crystals will contain about 60% anorthite—that is to say, they are enriched in the less fusible component. As crystallisation proceeds, the feldspar that separates becomes gradually less rich in anorthite. The composition of the liquid also alters, because the crystallisation is abstracting anorthite molecules more rapidly than albite molecules.

This process may go on till the feldspar has all crystallised, the last deposited being near albite in composition, and the crystals, examined microscopically, will show zones, of which the internal are rich in anorthite and the external are progressively richer and richer in albite. But if sufficient time is allowed, a reaction sets in between the crystals and the liquid; in other words, the feldspars crystallised are not in equilibrium with the magma except at the moment of crystallisation, and as the magma becomes richer in albite it will attack the early plagioclase, replacing it by a variety containing more albite. These phenomena are well known to petrologists as zonal structure of plagioclase feldspars; and corrosion of the cores and internal zones of the crystals is almost universal in such rocks as basalt and andesite. Rocks of similar composition which have

a glassy ground-mass will be formed, which is richer in soda and silica than the original magma and contains zoned feldspar crystals. This is exceedingly like what takes place in many basaltic lavas. Again, if the original mixture had been richer in feldspar, so that the composition point lay below the line DE, feldspar would have crystallised out first. This seems to be in keeping with the structure of many dolerites, which contain feldspar partly enclosed in augite crystals of later formation (ophitic structure), while others show that the augite appears in porphyritic crystals and began crystallising before feldspar. Another interesting feature of this diagram is that there is no tertiary eutectic point, and the liquid residue continually changes in composition up to its final disappearance.

The phenomena of these component systems are extraordinarily varied. One of the best known is the system  $\text{Al}_2\text{O}_3$ - $\text{CaO}$ - $\text{SiO}_2$  which has been very fully tested at the Geophysical Laboratory in Washington by Shepherd and Rankin. A copy of their diagram is given here (fig. 6). It is divided into fields, of which six are occupied by

FIG. 6.

substances known to occur as minerals, cristobalite, tridymite, wollastonite, anorthite, sillimanite and corundum. In each of these fields the mineral named will crystallise if the temperature of the melt falls. The fields are separated by lines which show under what circumstances the two minerals whose fields adjoin will crystallise. Where three fields meet, the conditions exist at which three minerals will exist simultaneously (or, to express it otherwise, are in equilibrium with a liquid of the composition indicated). In no case do four fields meet in one point.

This system is also of much interest to technologists desiring to understand the chemistry of the manufacture of Portland cement. This is a mixture of lime, alumina and silica, with a fairly definite composition, and the compounds which form on fusing or sintering the mixture are indicated by the diagram. Similarly, the  $\text{CaO}$  corner of the figure shows what is the result of heating lime containing a little alumina and silica (impure limestone) to a very high temperature. Silica is also a refractory mineral and is used in silica-bricks and ganisters for lining furnaces. A little lime and alumina are mixed with it (either naturally or expressly to obtain certain results), and the behaviour of such mixtures is indicated by the appropriate corner of the ternary scheme. These investigations accordingly are of the greatest value in many industries such as pottery, steel-making, glass-melting, brick-making, cement manufacture, lime-burning and the quartz-glass industry. It should be noted that the compound  $\text{Al}_2\text{SiO}_5$  which corresponds to the three common minerals of rocks, andalusite, sillimanite and kyanite should not be represented in this diagram. It has not yet been made in crucible melts. Another mineral, viz.: mullite, which has the composition  $3\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$  is produced under these conditions.

**Theory of Ternary Mixtures.**—The theory of ternary mixtures has been very fully worked out mathematically by Willard Gibbs, Backhuys Roozeboom, Schreinemakers, Smits, Kuenen, Tammann and others, and may be said to be well understood in its main applications. Experimental investigation has also made great progress. It is a laborious matter, requiring great skill and very elaborate appliances. The diagram we have given showing the ternary system  $\text{CaO}$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{SiO}_2$ , required over 7,000 experiments, in some of which the heating had to be continued for many hours and even for days; and the thermal results had usually to be checked by microscopic examination of the product. Other systems equally important have received very careful study. These are not so simple as the instance quoted, because mineral transformations, either during or after crystallisation of the melts, often give rise to many complications.

Thus, for example,  $\text{CaSiO}_3$  crystallises as pseudo-wollastonite at high temperatures, which may change to wollastonite at low temperatures.  $\text{MgSiO}_3$  has four forms—kuperite, magnesia amphibole, enstatite and clinoenstatite. Where both these substances separate from the melt, none of the above-named minerals appears, but a diopside clinoenstatite solid solution or isomorphous mixture, which belongs to the common group of minerals known as the pyroxenes.

These facts are of the greatest interest to both mineralogists and petrologists. They have introduced many new minerals (artificial) to our knowledge, and taught us their relationships at atmospheric pressures in certain dry melts. They have also enabled us to understand many of the peculiarities of the minerals that occur in rocks, and the method of their origin.

As another instance we may quote the relations of forsterite ( $\text{Mg}_2\text{SiO}_4$ ) and enstatite ( $\text{MgSiO}_3$ ). Forsterite may crystallise from melts of suitable composition and after a time it may become unstable in the residual magma; then it is dissolved up or "corroded" and clinoenstatite replaces it. Again, if an enstatite ( $\text{MgSiO}_3$ ) mixture be fused and allowed to cool, forsterite begins to separate out; it will tend to be reabsorbed and converted at a lower temperature to clinoenstatite, but if this be prevented the mixture solidifies as forsterite, clinoenstatite and quartz. To the petrologist this is of great interest, because forsterite is one of the constituents of olivine, a very common mineral of the basic igneous rocks. Now olivine generally occurs along with some member of the pyroxene group, and the olivine crystals show rounded outlines, which have been taken to indicate corrosion or resorption by the magma after crystallisation with concurrent formation of pyroxene. In some rocks there is clear evidence that olivine crystallised early and subsequently was entirely dissolved. In other rocks olivine is found enveloped in clusters of enstatite crystals which have evidently formed at its expense; and it is a very frequent characteristic of the olivines of gabbro and norite, that they are surrounded by "reaction rims" or "corrosion borders" consisting of enstatite, tremolite and other magnesian silicates that have a higher percentage of silica than olivine itself. The meaning of these phenomena was fairly well apprehended by petrologists, and now their conclusions have been confirmed by experimental evidence. Another feature of some interest is that, in the ternary system under consideration, it has been shown that forsterite may crystallise early, then disappear by corrosion, and a second generation of forsterite may subsequently crystallise. Whether this is a common phenomenon is not yet known, and its exact relation to the frequent appearance of minerals in two generations in rocks remains to be demonstrated.

The number of ternary systems that have as yet been fully investigated is small, though the results are of the highest importance. Those which contain the alkalis potash and soda present certain special difficulties, such as the volatility of part of the mixtures and the difficulty of crystallising some of the minerals. Rapid progress is being made and it is unlikely that experimental difficulties will retard the advance of knowledge. A special case, of the greatest possible interest to the petrologist, arises where one or more of the components are volatile. Natural magmas are probably always richly charged with gases. The theory of such systems has been explored by Schreinemakers, Smits and others. Experiments with mixtures enclosed in steel bombs which can withstand great pressures at high temperatures have been very successful in certain cases, but as yet only the borders of this field have been explored. A good deal of work has been done on the dissociation pressure of sulphides of the metals, a subject of great importance as regards the paragenesis of natural sulphides and the conditions under which mineral veins have been formed. The effect of steam in the formation of silicates is under investigation and during the next few years will probably be the subject of much research.

**Recent Developments.**—The most recent developments of petrological investigation have followed certain well marked lines such as the behaviour of systems of more than three components, the effects of volatile ingredients at high pressures and temperatures, the theoretical basis of metamorphic processes and the genesis of mineral ore deposits (including the changes that effect secondary enrichment). Systems with many components can be handled only by means of mathematical developments. For example, a tetrahedron will represent a four-component system, but for higher orders of complexity special methods must be used which as yet have only received a preliminary discussion. The complicated series of solid solutions which many common minerals represent (such as tourmaline, mica, pyroxene) have been discussed on these lines, but only the simplest rocks are suitable for this method. Another line of advance has been the treatment of rocks as systems of three or four minerals, each having a complex composition, and with certain precautions this gives useful results.

Constantly increasing attention is being given to the effects of volatile constituents in determining the minerals which form in rocks and the transformations which take place during and after solidification. The solubility of water and other gases in silicate glasses at various temperatures has been determined, and it is shown that some of them may contain from 8% to 25% of water.

The calcite series has been very completely investigated as a mixture of  $\text{CaO}$  and  $\text{CO}_2$ , and its relations and properties are well known. Such series as copper and oxygen; silica, potash and water, and the

nature of the bond by which the water in zeolites is held to the other components have received very detailed investigation. The pneumatolytic or post-consolidation effects of vapours set free by crystallisation have attracted more and more attention, especially the formation of zeolites, albitisation, analcitisation, scapolitisation and the production of mica at the expense of original feldspar.

In the study of metamorphism, new and fruitful advances have followed, especially the consideration of rocks as systems of mineral components in more or less complete equilibrium according to their composition and the conditions to which they are subjected. This was determined eventually by the phase rule, but the application is difficult, as rocks contain many components and no rock remains for an indefinite period in exactly the same conditions. An igneous rock, for example, has a gradually falling temperature, a metamorphic rock may suffer great changes in pressure or in temperature in the course of its history. Hence a simplified or modified phase rule must be devised for the case in hand. Still the broad fact remains that certain minerals may be expected to form in a rock of known composition according to the physical conditions to which it is exposed. The hydrous silicates of alumina, such as clay, are stable only at low temperatures; and are replaced by andalusite or sillimanite when the rocks are greatly heated, and generally by mica when there has been great pressure or movement. The recognition of distinct "facies" of rocks, each characterising special zones of pressure and temperature, has been carried to a great length by Swiss, Austrian and German petrologists, and is undoubtedly very helpful to the study of the science.

Along with this there has been an effort to classify mineral associations as groups of phases which may or may not occur together in stable equilibrium. For example, silica forms three minerals, each having more than one form (the commonest in rocks being quartz); alumina forms corundum; the combination of silica and alumina forms sillimanite, andalusite and kyanite (and also mullite). In a hypothetical rock consisting of silica and alumina, quartz and corundum should not occur together if the temperature has been raised above the point of combination. If we add magnesia to the two oxides mentioned above we get a further group of minerals such as enstatite, cordierite and spinel. Rules have been laid down which determine the associations of minerals which should occur together under various conditions in mixtures with the composition given above. In all this work the sciences of metallurgy, physical chemistry, and the crystallisation of saline solutions have exerted a very strong influence on petrological theory, and have stimulated research along new lines.

**BIBLIOGRAPHY.**—For the recent advances in physico-chemical and experimental petrology no English text-book is available. A Harker's *Natural History of Igneous Rocks* (1909) gives a sketch of the subject from the standpoint of its time, but is now out of date. A more adequate work is H. E. Boeke's *Physikalische-Chemische Petrographie* (1915), which gives full references and is the best general account. J. H. L. Vogt's *Silikatmelzungen* (1904) is interesting but very speculative. His *Sulphid-Silikatmelzungen* (1925), deals with some special aspects of the problem. The fundamental works on the theory of equilibrium are H. W. B. Roozboom's *Heterogenen Gleichgewichte*, vol. 1 (1901), vol. 2 (1904) and its continuation (vol. 3) by F. A. H. Schreinemakers (1911). See A. Findlay, *The Phase Rule* (1923); G. Tammann, *Krystallziren und Schmelzen* (1903). For English and American students the best authorities are the papers published by the workers of the Geophysical Institution in Washington. See also P. Niggli, *Lehrbuch der Mineralogie* (1920), *Die Leichtflüchtigen Bestandteile im Magma* (1920); R. A. Daly, *Igneous Rocks and their Origin* (1914); J. P. Iddings, *Igneous Rocks* (1913); A. D. Holmes, *Nomenclature of Petrology* (1920); J. Stark, "Petrographische Provinzen," *Fortschritte der Mineralogie* (1914); H. Rosenbusch, *Elemente der Gesteinslehre*, 4th ed. by Prof. Osann (1923); Jacques de Lapparent, *Leçons de Petrographie* (1923); F. Rinne, *Gesteinskunde*, 9th ed. (1923); A. Harker, *Petrology for Students*, 6th ed. (1923); H. Milner, *Sedimentary Petrography* (1922); a second edition of H. E. Boeke's *Physikalische-Chemische Petrographie* (ed. W. Eitel) has appeared (1923); O. H. Erdmannsdorfer, *Grundlagen der Petrographie* (1924); U. Grubenmann and P. Niggli, *Die Gesteinsmetamorphose*, 3rd ed., pt. 1 (1924); W. Eitel, *Physikalisch-Chemische Mineralogie und Petrologie* (1925); H. Rosenbusch and E. A. Wulff, *Mikroskopische Physiographie*, 1st vol. of 5th ed., (1925).

**PHARMACOLOGY** (see 21.347C).—The rapid growth of the science of pharmacology has been one of the most striking features of the development of the science of medicine (*q.v.*) during the present century. A knowledge of the functions of the body in health and disease is obviously a necessary preliminary to the study of the changes produced by drugs upon these functions, and hence the development of pharmacology has been dependent upon the development of the sciences of physiology, pathology and bacteriology.

**Organic Chemistry.**—The only substances available for medical use a century ago were certain inorganic salts and crude

vegetable extracts. The development of organic chemistry provided therapeutics with purified active principles of the crude vegetable extracts, and thus the use of crude preparations of unknown strength was replaced to a large extent by the use of chemical substances of known composition. Organic chemistry rendered a still more important service to pharmacology with the synthesis of organic compounds by which the number of substances available for use in therapeutics was increased indefinitely.

The anaesthetics, ether (1846) and chloroform (1847), were the first synthetic organic compounds to be used extensively in medicine. Twenty years later the first synthetic hypnotic, chloral hydrate, was introduced, and about 1885 the coal tar antipyretics, acetanilide and antipyrin, were discovered. Since then hundreds of new synthetic drugs have been discovered, and most of the important recent advances in pharmacology have been dependent upon the production of new synthetic drugs.

**Salvarsan.**—The discovery by Ehrlich in 1910 of salvarsan, a very potent remedy for syphilis, established a new method of research which has since yielded other results of great importance and promises to produce even greater successes in the future.

In his search for a substance which would kill the infectious organism of syphilis (*q.v.*), the *Treponema pallidum*, without injuring the patient, Ehrlich started with the knowledge that allied organisms, the trypanosomes, were killed by certain dyes and organic arsenic compounds. Not content with a random examination of the known compounds, he determined quantitatively which types of compounds were the most satisfactory for his purpose and then got new compounds prepared according to a definite plan. He made a systematic examination of a long series of organic arsenic compounds, determining in each case the minimal dose of the drug which would cure an animal infected with trypanosomes (minimal curative dose) and the maximal dose which the animal could tolerate (maximal tolerated dose). He termed the ratio:—

$$\frac{(\text{maximal tolerated dose})}{(\text{minimal curative dose})}$$

the therapeutic index, and sought for a drug with the highest possible therapeutic index. The compound salvarsan or arsenobenzole was the 606th arsenic preparation investigated, and in 1910 it was introduced as a remedy for syphilis. Two years later, Ehrlich introduced neosalvarsan or novarsenobenzole, which has to a large extent replaced salvarsan in the treatment of syphilis (see **VENEREAL DISEASES**). Ehrlich's brilliant success stimulated an intensive investigation of the action of organic metallic compounds upon diseases due to infections by animal parasites.

**New Methods.**—A number of important new methods of treatment have been discovered. Intramuscular injections of bismuth salts have been found to be of value in the treatment of cases of syphilis which are refractory to the organic arsenicals. Salts of antimony also have been found to have important new therapeutic actions. A century ago the production of subacute antimony poisoning by large doses of tartar emetic was a routine treatment for a very large number of diseases, but the revolt against the "heroic" methods of treatment of disease, in the middle of last century led to tartar emetic being almost abandoned as a therapeutic agent. The drug was discovered to possess the new and important therapeutic action of acting like arsenic as a specific disinfectant for animal parasites (see **HOOKWORM**). Intravenous injections of antimony salts have been found of great value in treating various diseases due to trypanosomal infection, and also have been found to cure the disease bilharziasis (*q.v.*).

Perhaps the most important internal disinfectant to be discovered is the compound "Bayer 205," a derivative of the dye trypan blue. This substance has a powerful action both in preventing and relieving the trypanosomal disease sleeping sickness (*q.v.*), the worst scourge of tropical Africa.

**Sanocrysin.**—The search for internal disinfectants with which to combat bacterial diseases has not achieved any very outstanding triumphs. Mollgaard has shown recently that an organic compound of gold, sodium aurithiosulphate, named "sanocrysin" can produce very remarkable curative effects, in a certain proportion of cases of tuberculosis (*q.v.*), but is equally capable of producing deleterious effects, and therefore great care is needed in its administration.

**Antiseptics.**—The special conditions of World War surgery made the discovery of powerful wound disinfectants an urgent problem, and a number of new disinfectant compounds of great activity were discovered, for example the dye "acriflavine," and the quinine derivatives "vuzin" and "optochin" (see ANTISEPTICS). Although the synthesis of the alkaloid quinine has not yet been effected, nevertheless its chemical structure is known, and it is possible to modify the structure of the alkaloid and thus produce new compounds. Vuzin and optochin are two quinine derivatives which differ from quinine in having a far more potent disinfectant action on bacteria. Another important new wound disinfectant is chloramine-T, an organic chlorine compound which acts by slowly liberating chlorine. The disinfection of the kidney and the bladder is another important problem in which advances recently have been made. A new organic compound termed hexyl resorcinol appears to be a more powerful urinary disinfectant than any previously known.

**Use of Active Principles.**—Most of the advances mentioned hitherto have depended upon the discovery of new synthetic organic compounds of greater potency than any known hitherto, but cures for other diseases have been discovered by substituting purified active principles for crude vegetable extracts.

Ipecacuanha has been known for more than a century to benefit amoebic dysentery, but the administration of the drug by mouth was limited by its action as an emetic. Sir Leonard Rogers showed in 1912 that subcutaneous injections of the alkaloid emetine, the chief active principle present in ipecacuanha, usually produced a rapid cure in cases of amoebic dysentery (see DYSENTERY).

Similarly, it has been known for many years that leprosy (*q.v.*) is often benefited by administration of Chaulmoogra oil, but it was found impossible to administer large doses of this oil by mouth on account of its irritant properties. Organic chemists isolated from Chaulmoogra oil certain complex fatty acids named hydnocarpic and chaulmoogric acids, which were believed to be the chief active principles present in the oil. Sir Leonard Rogers in India and Heiser in the Philippines introduced the method of injecting preparations of these purified fatty acids intravenously or intramuscularly and obtained remarkable curative effects even in the cases of leprosy of many years' duration (see LEPROSY). The most striking recent successes of pharmacology have been achieved in the cure of infectious diseases, because in most other serious diseases some vital organ has received irreparable damage, which drugs may alleviate but cannot cure.

**Anaesthetics.**—Important progress has, however, been made in the discovery of drugs needed to produce certain temporary alterations in the functions of the body. General anaesthetics are perhaps the most important group of drugs of this class. In 1924 and 1925 acetylene and ethylene were tried as substitutes for nitrous oxide, but at present it is doubtful whether the new gases will prove to have any marked superiority over nitrous oxide.

Many drugs produce some very useful action but have in addition some highly undesirable side action. Cocaine, for example, is an excellent local anaesthetic, with the grave disadvantage of sometimes producing dangerous effects on the brain. Of the large number of local anaesthetics, which have been synthesised in the hope of producing some complete substitute for cocaine, Novocaine is one of the best known and can replace cocaine completely for many but not for all purposes. Since 1910 a number of new compounds of great potency as local anaesthetics have been discovered, and probably it will soon be possible to avoid the use of cocaine almost completely.

**Hypnotics.**—Similarly, a host of new and very potent hypnotics have been synthesised in the hope of finding a reliable hypnotic which will not produce a habit, and is perfectly safe. Unfortunately, not much advance has been made in this field. In a few cases important new uses have been discovered for drugs which have been known for many years, such as the discovery in 1918 that quinine, one of the alkaloids present in Cinchona bark or Jesuit's bark, can cure the important disorder of the heart known as auricular fibrillation.

**Physiological Features.**—The accurate analysis of the mode of action of drugs of well-established reputation has in certain cases greatly increased their value, making it possible to increase their dosage with safety and thus ensuring that sufficient of the drug is given to produce the physiological effect desired. The administration of digitalis in heart disease is a case where considerable improvements in technique of this character have been effected in recent years.

The study of the actions of extracts of the glands of internal secretion (see ENDOCRINOLOGY) is a field common to physiology and pharmacology. In 1886 it was shown that the two diseases myxoedema and cretinism, due to deficiency of the thyroid secretion, and previously considered completely incurable, could be cured by the simple remedy of administering dried thyroid gland by the mouth. In 1922 Banting obtained an extract from the pancreas, which he termed insulin (*q.v.*), and which he proved would relieve the disease of diabetes mellitus (*q.v.*).

**Internal Secretions.**—There are peculiar difficulties attending the study of the secretions of the endocrine glands. Active principles have been obtained from the parathyroid glands and the ovaries which also promise to be of value as agents for substitution therapy, where the normal secretions of these organs are deficient. Substances have been obtained from other endocrine organs which have no certain value as agents for substitution therapy but are drugs with powerful and interesting pharmacological actions. One such substance, adrenalin, was discovered in 1896, and has been found of great value in producing constriction of small arteries and thus acting as a haemostatic.

Extracts of the posterior lobe of the pituitary gland produce a rise of blood pressure and constriction of plain muscle and since 1916 this extract has been brought into therapeutic use, and is now very extensively used to cause contraction of the uterus, and thus to accelerate childbirth and to prevent the disastrous complication known as post-partum haemorrhage.

**Vitamins.**—The vitamins (*q.v.*) are biological products which have important pharmacological actions. They are unstable bodies of unknown chemical composition which are present in minute amounts in a large variety of fresh foods, but usually are absent in preserved foods. Several vitamins exist, and a regular supply of all of them is essential to normal development and health. Scurvy and rickets are two examples of diseases caused by vitamin lack. Lemon juice has been known for more than a century to be a specific cure for scurvy, and biochemists have now succeeded in concentrating the vitamins of lemon juice so that a child suffering from infantile scurvy can be given the vitamin equivalent of 20 lemons in a single day. Similarly, cod liver oil has long been recognised as a cure for rickets, and the vitamin of cod liver oil has also been prepared in concentrated form. The practical need for such preparation will, one hopes, be small in the future, for the knowledge gained regarding vitamins ought to result in the disappearance of these deficiency diseases. The most striking recent advances have been made along two lines, firstly in the synthesis of drugs which will kill parasites that produce disease, and secondly in the isolation of biological products with important pharmacological actions.

**Parasitology.**—The disease-producing parasites are of two classes, firstly the animal parasites such as the trypanosomes, and secondly the vegetable parasites, the bacteria. Very remarkable successes have attended the preparation of internal disinfectants for the animal parasites, and cures have been found for a number of the worst diseases that afflict mankind; in particular, cures have been discovered for a number of very serious tropical diseases (*q.v.*). Less striking success has attended

the endeavour to find disinfectants that will kill bacteria infecting the body, but a certain amount of progress has been made, and any advance in this field is of the greatest importance to the inhabitants of temperate climates, because most of the worst infectious diseases of the temperate zone are bacterial in origin.

**BIBLIOGRAPHY.**—The most important work for general reference is A. Heffter, *Handbuch der Experimentelle Pharmakologie*, 3 vol. (1920); see also A. R. Cushny, *Pharmacology and Therapeutics*, 8th ed. (1924); W. E. Dixon, *Manual of Pharmacology*, 6th ed. (1925); A. J. Clark, *Applied Pharmacology*, 2nd ed. (1926). (A. J. C.)

**PHARMACY** (see 21.355).—The International Congresses of Pharmacy, held at intervals from 1865 to 1913, brought the pharmacists of various countries together and afforded opportunity for the discussion of questions of international importance. A considerable amount of time and effort was expended in the endeavour to produce an international Pharmacopoeia and to ensure that all medicinal preparations should be the same, no matter in what country they were prescribed. The attempt failed, but it paved the way for the adoption of useful international regulations.

### I. INTERNATIONAL PROGRESS

The congress held in Paris in 1900 recommended that a comparative table should be prepared showing the difference in the strength of medicaments bearing the same name in different pharmacopoeias; that the table should be distributed to medical and pharmaceutical authorities with the request that the possibility of unifying the strength should be considered; and that the Belgian Government be asked to convene a conference of accredited delegates from various nations with a view to arriving at a generally acceptable conclusion. This conference met in Sept. 1902 and issued a list of preparations upon which agreement as to strength had been reached. An international agreement embodying this list was signed in 1906 by the representatives of 18 nations and, substantially, all the decisions contained in it have been observed in the new issues of the pharmacopoeias of the signatory nations subsequent to that date.

A similar conference was held in Paris in 1925 to revise some of the decisions of the first conference and to take further steps towards the unification of the pharmacopoeial formulas for potent drugs and their preparations. Thus very important progress has been made towards international uniformity, at least in such drugs and preparations as most require it.

The 10th international congress held at Brussels in 1910 decided to establish a *Fédération Internationale Pharmaceutique* for the protection of pharmacy as a profession and as an applied science. The federation was established in 1912 at The Hague with Prof. Van Itallie and Dr. Hofman the first president and secretary respectively. Twenty-four national societies of pharmacy are now included in it, although Austria, Denmark, Germany, Hungary and Russia have retired since the World War. The last meeting of the international congress of pharmacy was held at The Hague in 1913. The *Fédération Internationale Pharmaceutique* has replaced it and has held meetings in 1922–3–4–5. Among the subjects discussed were pharmaceutical education, pharmaceutical nomenclature, pharmaceutical proprietary preparations, and the unification of the methods of assay.

**Modern Pharmacy and Science.**—The demands made upon the scientific knowledge and technical skill of the pharmacist have continually increased as shown by successive editions of the British, United States and other pharmacopoeias. The definition of the drugs has become more precise; tests of identity, limits of impurity, methods of assay have been introduced, and the use of the microscope required for the examination of many vegetable drugs. The introduction into medical practice of countless synthetic chemicals, of such organotherapeutical substances as the thyroid gland, pituitrin, etc., and of various vaccines and sera has imposed upon pharmacists the necessity of special study in order to understand them. The same may be said of the X-rays, and of the vitamins, the latter, in an impure form, being used in the form of compressed tablets or of capsules. Hypodermic injections are now commonly supplied sterilised and in ampoules, and the pharmacist must therefore be acquainted with the principles of sterilisation and with the action upon sensitive alkaloids of the heat used and the alkalinity of the glass of which the ampoules have been made.

**The Qualifications of the Pharmacist.**—In addition, therefore, to a knowledge of chemistry and botany as applied to pharmacy the pharmacist must be an expert microscopist. He must keep himself informed as to the new developments of therapeutics

and must be competent to supply such medicines as the physician may prescribe. Disinfection and hygiene also come within his purview. To ensure his competency the *Fédération Internationale Pharmaceutique* agreed that the following subjects should find a place in the studies of the pharmaceutical student: chemistry (analytical, biological, physiological and pathological), pharmacy (chemical and galenical), pharmacognosy, micrography, toxicology, hygiene, legislation, pharmacology, botany, microbiology, mathematics, crystallography, disinfection, sterilisation and optics—a somewhat formidable list.

**Modern Developments.**—Developments in the treatment of diseases and in the nature and quality of the remedial agents required, which are the outcome of scientific research, have a direct bearing upon pharmacy. Barger, Dale, Carr, Stoll and others have shown that the important drug, ergot, contains two extremely powerful alkaloids, ergotoxine and ergotamine, upon which its activity chiefly depends, accompanied by various amines such as tyroamine and histamine, which possess a subsidiary efficacy. The two alkaloids are soluble in alcohol but insoluble in water and are easily converted into two inactive substances from which they can be regenerated. These discoveries opened the way to a rational galenical preparation of ergot which has proved very satisfactory.

For a long time the group of oxymethylantraquinone drugs, which includes a number of purgative drugs such as rhubarb, cascara sagrada, etc., had baffled investigators as the crystalline oxymethylantraquinones or their glucosides failed to explain, quantitatively at least, the action of the drugs. Maeder has isolated from elder buckthorn bark the glucoside glucorhamnin in which two sugar groups are present. The laxative action of glucorhamnin is such that the amount present in the drug corresponds to the activity of the latter. Probably similar glucosides will be found in other members of the group. Kiefer, working upon Cape aloes, showed that the resins previously considered inactive were, on the contrary, strongly purgative and isolated the substance to which the gripping action was due and so made an important step towards a rational preparation of aloes. Bourquelot showed that many enzymes possess a synthetical as well as analytical action and prepared a number of synthetical glucosides and demonstrated the possibility of producing in the laboratory an entirely new class of compounds.

**Stabilisation of Drugs.**—Pharmacists have long desired to make from drugs galenical preparations which should contain the active constituents in the condition in which they exist in the plant. Goris and Arnould made an important step towards solving this problem by proving that the caffeine in fresh kola nuts exists in combination with kolatin, a combination which is broken up by an oxidase present in the fresh nuts. This oxidase can be rendered inactive by steam or alcohol vapour and the combination then remains unaltered when the nuts are dried and preparations made from them. Such treatment, or "stabilisation," of a drug will probably be extensively adopted. There is no doubt that, as in the case of kola nuts, the stabilised drug will frequently possess a therapeutic action different from the drug that has not been stabilised, and investigations along this line are being attempted.

**Medicinal Plants.**—During the War large quantities of medicinal plants were collected in Great Britain, partly wild, partly cultivated. Attempts to place the cultivation upon a satisfactory footing failed, owing to the difficulty of obtaining assistance for the young industry. In France the Government afforded every aid, and under the direction of Perrot the industry is rapidly growing and much information is being collected as to the effects of soil, manures, etc., necessary to produce the best results. In the United States considerable attention has been devoted to selection experiments with drug plants, and marked progress has been made towards the production of the most suitable strains. The extremely high price of santonin led to a search for other sources of that important vermifuge. Greenish and Pearson showed that *Artemisia brevifolia*, which grows in abundance in Northwest India, contained sufficient santonin to make it a possible source of that substance. Van der Wielan

and Van Laren have cultivated in Holland a species of *Artemisia* which also contains santonin, so that cheaper supplies of the drug are only a question of time. Wallis and Mowat have studied the characters of the genus and thrown much light on the botanical source of the *santonica* of commerce. Wallis has also devised a satisfactory method for the quantitative determinations by means of the microscope, a problem to which much attention had been given.

## II. CONDITIONS IN GREAT BRITAIN

The Poisons and Pharmacy Act of 1908 allowed a body corporate, and in Scotland a firm or partnership, to carry on the business of a pharmaceutical chemist or chemist and druggist provided that the business, so far as it related to the keeping, retailing and dispensing of poisons, was under the control of a registered pharmaceutical chemist or chemist and druggist. In the second place powers were given to the Pharmaceutical Society to divide the qualifying examination into two parts and to require candidates for the examination to produce satisfactory evidence that they had received a sufficient preliminary practical training in the subjects of the examination.

Before the necessary by-laws and regulations could be framed the society was involved in investigations and discussions preliminary to the National Insurance Acts of 1911 and 1913 by which the supply of drugs and medicines to insured persons was restricted to persons, firms and bodies corporate entitled to carry on the business of a chemist and druggist under the Pharmacy Acts of 1868 and 1908, thus admitting for the first time the important principle that the proper function of the physician is to diagnose and prescribe, and that of the pharmacist to supply the drugs and medicines so prescribed.

*Educational System in Great Britain.*—In 1920 the by-laws and regulations necessary for carrying the provisions of the Act of 1908 into effect were drawn up. They come into full force at dates varying from Feb. 1 1927 to Aug. 1 1929 and may be briefly summarised as follows:—

Before presenting himself for examination the candidate must have been registered as a student of the Pharmaceutical Society for which purpose he must have passed one of a number of entrance examinations ranging from the junior local examination of Cambridge or Oxford to the matriculation examination of the University of London. After registration he may proceed to the preliminary scientific examination, for which attendance at an approved systematic course of instruction of at least 440 hours in chemistry, botany and physics is necessary. Having passed this, or one of several alternative examinations, he will have to decide whether he will be content with passing the chemist and druggist qualifying examination or aim at the higher qualification by training for the pharmaceutical chemist qualifying examination. In the former case, when giving notice, he must produce a declaration that he has been trained under the direct supervision of a pharmacist in the dispensing and compounding of medicines for 4,000 hours spread over not less than two years in a pharmacy or in the dispensary of a hospital or similar institution approved by the council. He must also have attended an approved systematic course of at least 720 hours in pharmacy, pharmaceutical chemistry, pharmacognosy and forensic pharmacy.

If the candidate elects to proceed from the preliminary scientific examination to the pharmaceutical chemist qualifying examination, then he must be trained for at least 2,000 hours in a pharmacy or hospital and have attended an approved systematic course of at least 1,600 hours in botany, chemistry, pharmacognosy, pharmacy and forensic pharmacy. These statutory examinations are conducted by the Pharmaceutical Society.

The University of London has instituted the degree of bachelor of pharmacy in the faculty of medicine. To obtain this degree the candidate must have passed the matriculation examination of the university or an examination that would be accepted by the university in lieu of matriculation. At the intermediate examination in science, the subjects of botany, chemistry, physics and zoology or general biology are taken. For the final examination the course of study includes botany, chemistry, pharmacognosy and pharmacy and extends over two years. The candidate who has obtained the degree and wishes to practise pharmacy under the Pharmacy Acts must pass, in addition, an examination conducted by the Pharmaceutical Society in forensic pharmacy and must also have been trained for at least 2,000 hours in compounding medicines under a registered pharmacist in a

pharmacy or in an approved hospital or similar institution. He will then be entitled to be placed upon the register of pharmaceutical chemists. He can also proceed to other university degrees. The universities of Manchester and Glasgow also confer the degree of B.Sc. with pharmacy as one of the subjects, but these degrees cannot at present be utilised for the purpose of registration.

Thus, whereas in 1920 there was no compulsory curriculum of any kind, the entrant into pharmacy will hereafter undergo what is practically a two years' approved systematic course of training for the lower qualification and a three years' for the higher; in addition, if he has matriculated, university degrees are open to him. This achievement places the pharmaceutical student in Great Britain on a level with those of most other countries. The Pharmaceutical Society has the power of according or withholding approval of the schools or institutions desirous of training candidates as well as of the courses given, and by this means exercises effective control over the education of the pharmacist.

*Sale of Poisons.*—Since the passing of the Poisons and Pharmacy Act in 1908 the number of substances brought within the range of Part I. of the schedule (those substances which may not be sold to any person unknown to the seller unless introduced by a person known to both parties and of which the sale must be duly registered) has been considerably increased. It now includes the following substances:—

Aconite, aconitine and their preparations; all poisonous alkaloids not specifically named, and their salts and all poisonous derivatives of alkaloids; arsenic and its preparations; atropine and its salts and their preparations; belladonna and all preparations or admixtures (except belladonna plasters) containing 0.1 % or more of belladonna alkaloids; cannabis (the dried flowering or fruiting tops of the pistillate plant of *Cannabis sativa*) and the resins prepared therefrom. Cantharides and its poisonous derivatives; coca, any preparation or admixture of, containing 0.1 % or more of coca alkaloids; corrosive sublimate; cyanide of potassium and all poisonous cyanides and their preparations; diamorphine (also known as heroin) and all preparations or admixtures containing 0.1 % of diamorphine; diethyl-barbituric acid and other alkyl, aryl or metallic derivatives of barbituric acid, whether described as veronal, propional, medinal or by any other trade name, mark or designation; and all poisonous urethanes and ureides; digitalin and all other poisonous constituents of digitalis; ecgonine and all preparations or admixtures containing 0.1 % of ecgonine; emetic tartar and all preparations or admixtures containing 1 % or more of emetic tartar; ergot of rye and preparations of ergots; lead in combination with oleic acid or other higher fatty acids, whether sold as diachylon or any other designation (except machine-spread plasters); nux vomica and all preparations or admixtures containing 0.2 % or more of strychnine; opium and all preparations or admixtures containing 0.2 % or more of morphine; picrotoxin; prussic acid and all preparations or admixtures containing 0.1 % or more of prussic acid; savin and its oil and all preparations or admixtures containing savin or its oil; strophanthin and all other poisonous constituents of strophanthus; tobacco, any preparations or admixtures of (other than tobacco prepared for smoking and snuff), containing the poisonous alkaloids of tobacco.

The changes that have been made in Part II. of the poison schedule (those that must be labelled poison) are small; salts of barium (except barium sulphate) and zinc chloride and its liquid preparations, except those intended for industrial purposes, have been included and coca has been deleted.

By the Dangerous Drugs Act 1920-3 further restrictions have been placed upon the sale of morphine, cocaine, ecgonine, diamorphine, heroin and their respective salts and medicinal opium. Generally stated, these drugs may, with certain exceptions, be supplied only to physicians' prescriptions and a record must be kept of the quantities bought and sold.

*Other Countries.*—In the United States of America and in most other countries analogous regulations have been adopted for controlling the sale of poisonous drugs.

The Labelling of Poisons Order, which came into force on Jan. 1 1926 imposes further conditions upon the sale of poisons (whether contained in Part I. or Part II. of the schedule). This Order and the Act under which it is made require that, in general, every preparation containing as an ingredient any poison to which the Pharmacy Act 1868, as amended, applies shall bear on the label a statement of the proportion which such poison bears to the total ingredients of the preparation. By this means control is exercised over the sale of poisons forming constituents of proprietary or secret preparations. The *Fédération Internationale Pharmaceutique* is endeavouring to formulate a scheme for the uniform treatment of such preparations by all the States included in it.

Evers, *Chemistry of Drugs* (1926); *Pharmacopoeia of the United States* (1926). (H. G. G.)

**PHILADELPHIA** (see 21.367), retaining its rank as third city of the United States, had in 1920 a population of 1,823,779, an increase of 274,771 over 1910; and in 1925 (U.S. census estimate) 1,979,364. The population of 1920 comprised whites 1,688,180; coloured 135,599. The increase in the white population since 1910 was 224,809, or 15.4%; while the corresponding increase in the coloured population was 49,962, or 58.3%.

**Government and Finance.**—The Bullitt Act, under which the city government had functioned since 1887, gave way in 1920 to the Woodward Act, which became effective with the beginning of the term of Mayor J. Hampton Moore in Jan. 1920. The new charter differs greatly from its predecessor. Under it a dual council is succeeded by a single body composed of one member for each 20,000 assessed voters in each state senatorial district, the membership in 1920 being 21. The councilmen serve for four years. The small council has shown its superiority over the earlier system in many ways; its great weakness is the lack of a system of minority representation. In the executive department, the department of supplies is superseded by a purchasing agent; and the department of health and public charities is separated into two departments with a director for each. Further provisions require a municipal budget system, enable the city to do its own street cleaning and garbage and ash removal and place the great majority of city employees under civil service rules.

The cost of city operations has grown steadily since 1911, when, under provisions of the state school code of May 18 1911, the Board of Education was separated from the city government. The combined cost in 1911 was \$33,846,875. With the school expenses eliminated, the cost in 1912 of city government was \$30,213,067; and, barring a slight decrease in 1913, it has grown steadily until it reached \$70,531,801 in 1925. The tax rate, excluding school tax, was \$1 in 1912, and \$1.75 in 1922-6. This rate applied to real estate valued in 1926 at \$2,940 million. On Jan. 1 1925, the gross funded outstanding debt of the city was \$225,967,200, of which the commissioners of the sinking fund held \$58,117,900. The interest and sinking fund amounted in 1925 to three-eighths of the tax levy.

**Commerce and Industry.**—As a manufacturing centre Philadelphia shared the general depression of 1914, but advanced rapidly with the European demand after the outbreak of the

World War, dropping again after the War. Exports and imports of the Philadelphia customs district for recent years are shown (in thousands of dollars) in the following table:—

|                | Exports | Imports |
|----------------|---------|---------|
| 1910 . . . . . | 73,266  | 88,403  |
| 1915 . . . . . | 90,666  | 72,948  |
| 1920 . . . . . | 442,250 | 282,163 |
| 1921 . . . . . | 130,672 | 122,302 |
| 1922 . . . . . | 126,477 | 154,332 |
| 1923 . . . . . | 106,508 | 219,710 |
| 1924 . . . . . | 106,444 | 202,597 |
| 1925 . . . . . | 119,064 | 215,343 |

The net tonnage of vessels entered at and cleared from Philadelphia customs district from and for foreign countries in recent years was as follows:—

|                          | Entered   | Cleared   |
|--------------------------|-----------|-----------|
| 1910 (June 30) . . . . . | 2,606,097 | 2,250,489 |
| 1915 (June 30) . . . . . | 1,938,510 | 1,786,441 |
| 1920 (Dec. 21) . . . . . | 3,518,865 | 3,806,981 |
| 1921 (Dec. 21) . . . . . | 2,866,630 | 2,530,244 |
| 1922 (Dec. 21) . . . . . | 3,126,399 | 2,601,711 |
| 1923 (Dec. 21) . . . . . | 2,930,003 | 2,204,710 |
| 1924 (Dec. 21) . . . . . | 2,363,623 | 2,097,822 |

A remarkable increase in the activities of the port was made possible by the completion of large parts of the 35-ft. channel from Allegheny ave., Philadelphia, to the sea. The channel, about 800 ft. wide throughout, was 80% completed on Dec. 1 1925, the remaining sections having a depth of 30 feet. The completion of the deeper channel opened the port to shipping of a heavier tonnage, and the result was manifest in the increased number of lines plying from Philadelphia. In 1914 there were 27 transatlantic and 5 coastal lines; in April 1921, 49 transatlantic and 10 coastal lines. Philadelphia in 1919 had 9,064 manufacturing establishments, with 281,105 employees, and products of \$1,996 million. Metals and metal products were first, and textile production next, followed by food products, chemicals, clothing, paper and printing, leather and rubber products.

**History.**—Municipal history during the period 1910-8 was marked with few items of interest outside the political aspect and the natural effect of American participation in the World War. Between 1919 and 1925 many much-needed and long-discussed public works were undertaken; and among those already finished are the Parkway from City Hall to Fairmount Park, the Roosevelt Boulevard in the northeastern part of the city, the Cobb's Creek Parkway on the western boundary, and the Frankford elevated railroad. In 1926 a suspension bridge across the Delaware river, with a span of 1,750 ft., connecting with the city of Camden, N. J., was completed, as were also a beautiful free library building and the exterior of the municipal art gallery. This building stands on an Acropolis-like hill at the end of the Parkway and furnishes an imposing view from that avenue. A four-track subway, six and a half miles in length, is under construction on North Broad street; contracts for \$61,000,000 had been let in 1925 and it was expected to be completed in 1927. The improvement of the harbour has been pressed forward, the latest (the 12th) modern municipal pier being completed in 1925 at a cost of \$3,662,000. A plan, jointly financed by the railway and the city, has been adopted for the relocation of the elaborate system of terminals and trackage of the Pennsylvania railroad.

Preparatory to the celebration of the 150th anniversary of American independence in 1926, a municipal stadium, a convention hall, exhibition buildings, aviation fields and other accessories were in 1925 being constructed in south Philadelphia. The late John G. Johnson, who died April 14 1917, gave the city his collection of 1,300 pictures, appraised at \$4,445,802. In May 1919, the art collection of Mrs. Emily L. Harrison was left to the Pennsylvania Museum and School of Industrial Art for permanent exhibition in Memorial Hall. In Oct. 1919, the George W. Elkins collection of paintings, containing 110 masterpieces of the Dutch, Flemish and 18th-century portrait schools,

was left to the city for display in the new art museum. In 1921 the late John Howard McFadden, a cotton broker, left to the municipality his collection of about 50 18th-century English paintings. The collection included the Gainsborough "Lady Rodney" and portraits by Romney and Raeburn. (A.E.McK.)

**PHILATELY:** see STAMP COLLECTING.

**PHILIPPINE ISLANDS** (see 21.392).—A group of 7,083 islands of the Malay archipelago, with an area of approximately 115,026 sq. miles. About 64,000 sq. m. of the area represent commercial forests; the area of the cultivated lands is about 14,000 sq. miles. The total population in 1922 was 10,906,482, the majority of whom were Christians, the remainder of the population consisting of Mahomedans, Buddhists and pagans. The population of Manila, the largest city, was 285,306 in 1918; that of Cebu was 65,502 in the same year; Albay, 52,756; Iloilo, 49,114; Lepa, 46,557. Some 87 languages and dialects are spoken throughout the islands, the most important being Tagalog, Bisaya (several dialects), Bicol, Pampanga, Pangasinan, Iloco, Zambal and Ibanag. English is spoken by about 30% of the population and Spanish is spoken by 20 per cent.

## I. GENERAL

**Government.**—The Philippines are represented in the United States by two resident commissioners who have seats in the House of Representatives, with power of debate but no vote. The archipelago has a high measure of self-government. With the exception of the governor-general, vice-governor, auditor, deputy auditor and a majority of the members of the Supreme Court (but not the Chief Justice, who has always been a Filipino), all the higher officials, whether executive, legislative or judicial, are Filipinos. The islands are governed under the terms of the enabling or organic Act of Aug. 29 1916, commonly known as the Jones Act. The legislature consists of a Senate of 24 members and a House of Representatives of 91 members. All the legislators are elected by popular vote except two senators and nine representatives, who are appointed by the governor-general to represent the non-Christian provinces of Sulu and Zamboanga, Nueva Vizcaya, Mountain Province, Agusan, Bukidnon, Cotabato, Davao and Lanao.

Thus far, although there are two political parties in the field, the Philippines have not enjoyed a healthy party life; but there are signs that this condition will change as more and more of the young men who have been trained wholly under the American régime take their place among the voters. The two parties are the Consolidated Nationalist party (*Partido Nacionalista Consolidado*) and the Democrats (*Partido Demócrata*). The first is the more radical of the two, and has made an issue of the demand for immediate and absolute independence. The *Partido Demócrata*, while expressing itself in favour of independence, appears to be in favour of allowing political events to shape themselves more slowly. The number of qualified electors is in excess of 1,000,000; and in the general election of 1922 it was reported that 812,000 had actually voted. Gov.-Gen. Wood has recommended that the suffrage be extended to women.

The judiciary consists of a Supreme Court composed of one Chief Justice and eight associate justices, modelled largely after the Supreme Court of the United States; a court of first instance for each judicial district, except the district of the city of Manila, which has four judges; the municipal courts of Manila and Baguio; and a justice of the peace court for each of the 555 municipalities.

**Defence.**—Maintenance of public order in the Philippines devolves upon the municipal police and the Philippine constabulary. In 1914 the strength of the constabulary was 396 officers and 6,325 enlisted men of all ranks. The force was distributed throughout the islands amongst 149 stations. A force consisting in 1924 of about 12,000 troops of the U.S. Army, including five Filipino regiments, was maintained in the Philippines by the United States.

**Education.**—Education is free in all the public schools of the Philippines. The vice-governor is secretary of public instruction. In 1918 it was estimated that 24.46% of the school population

were enrolled in the public schools. By 1923 the percentage had risen to 36.69%. The elementary teaching force in 1923 numbered 24,190; secondary teachers, 933; and supervisors, 657; while in 1918 there were only 14,523 teachers of all grades. Of the 1,087,732 elementary pupils in 1923, 634,350 were boys and 453,382 were girls. Of the secondary school pupils, 27,972 were boys and 13,293 girls. Of the teachers, in Dec. 1923, 15,327 were men and 10,453 women. Among them were only 368 Americans, of whom 177 were men and 191 women. Efforts were being made to increase the number of American teachers. Greater attention is given to health and sanitation in the public schools, and athletics are a recognised part of the curriculum.

The university of the Philippines is an insular government institution that was created since American occupation. It has schools of agriculture, education, engineering, liberal arts, law, medicine and surgery, veterinary science, dentistry, pharmacy, music, nursing, fine arts and forestry, a junior college of liberal arts and a university high school. Enrolment in all units for the academic year 1918-9 was 3,312; for the year 1923-4, 5,994. The university has had two American and two Filipino presidents, the incumbent in 1926 being a Filipino, Rafael Palma, who had formerly been a member of the Philippine commission, and had acceptably held other offices of trust under the Government. Expenditures for the university amounted to approximately 1,197,000 pesos for the year 1919 and to 1,717,000 pesos for 1923. There are many private schools, partly religious and partly secular, and many new parochial schools have been established. Among private institutions, the Silliman Institute and the Ateneo of Manila occupy high places, and the University of Santo Tomás, the oldest university under the American flag, has played an important part in the history of the islands.

**Finance.**—The peso, practically stabilised at 50 cents United States gold currency by the operations of a gold standard and reserve fund, is the standard of value. It fluctuated considerably after 1916, reaching a discount of 15% in 1919 and over 12% in 1921, but is once more approximately at par. The estimated wealth of the Philippines in 1918 was 4,252,789,000 pesos, and in 1923, 5,495,482,000 pesos. The total wealth is capable of very great expansion as the potential resources are developed. The receipts of the Insular Government for the years 1918, 1920, 1921 and 1923 were 68,690,105 pesos; 99,404,913 pesos; 130,199,714 pesos and 71,108,722 pesos respectively; and ordinary expenditures for the same years were 57,496,044 pesos, 84,010,279 pesos, 118,194,211 pesos and 95,589,800 pesos, respectively. The total insular bonded indebtedness on Dec. 31 1923 amounted to 134,500,000 pesos; city of Manila collateral bonds, 5,500,000 pesos; provincial and municipal bonds, 13,920,000 pesos; making a total bonded debt on Dec. 31 1923 of 153,920,000 pesos. The total *per capita* debt rose from 2.81 pesos in 1919 to 12.26 pesos in 1923.

**Production and Industry.**—In the production of coconuts the Philippines rank amongst the foremost countries of the world, and this product has contributed largely to the economic progress of the islands. The nut furnishes copra, copra meal, coconut oil and butter, vinegar, desiccated coconut; and from the fibre of the outer husk coir mats and other articles are made. Rice production always falls short of consumption because farmers consider other crops more advantageous, and imports (mainly from French Cochín China) are necessary. Next to rice, maize is the most universal grain food, maintaining about 24% of the population. The sugar crop is steadily increasing in importance, especially since the installation of sugar centrals, where centrifugal sugar is made. Abacá, or manila hemp, the strongest commercial fibre known, has always been one of the principal crops; and upon its prosperity largely depends. As it can be grown successfully in no other region, the Philippines have a natural monopoly. It is extensively used in the manufacture of hats and textiles. Maguey, much inferior to abacá, is grown especially for the manufacture of binder twine. The Philippines are one of the chief tobacco-raising countries in the world. Exports of tobacco leaf and manufactures of tobacco were valued at 21,034,893 pesos in 1923 and 19,725,718 in 1924.

**Livestock.**—Carabao, the main dependence of the peasants, numbered 1,541,000 in 1922; cattle, 815,000; horses, 204,200; hogs, 5,241,200; goats, 1,012,600; and sheep, 257,700. Anthrax and rinderpest are among the most serious problems of the Philippines.

**Forest and Forest Products.**—The commercial forests are estimated to contain 200,000,000 board ft. of lumber, comprising both hard and soft woods. The Government owns about 99% of all standing timber. Public forests are not sold, but the exploitation of timber lands is granted by licence or concession. Among the most valuable of the forest products are rubber, bamboo, rattans, gutta-percha, gum copal, various resins, dyestuffs, tanbark and beeswax.

**Minerals.**—The output of gold increased from 141,209 fine grammes in 1907 to 2,537,162 grammes in 1923. Silver is found with the gold minerals, but native silver occurs in small quantities in Benguet and Mindanao. Iron deposits occur in Surigao (estimated at 500,000 metric tons), Bulacan (1,200,000 tons), and Camarines Norte. Although coal was discovered as early as 1827, workings have been so far slight and unsatisfactory in their output.

**Manufacturing and Other Industries.**—Agriculture is the most important basis of what manufacturing is carried on. Besides the manufacture of sugar and tobacco, abacá is made into cordage and textiles; various products into perfumes; fibrous substances into the famous Philippine hats; rattans and woods into furniture and other articles; vegetable compounds into soap; barks of the mangrove and camanchell tree into tanning materials; and various plants into dyes. Embroideries exports rose from a mere beginning in 1915 to about 12,000,000 pesos in 1923. Fishing ranks second to agriculture in the value of the product and the number of persons employed in it.

The following table shows the area under cultivation, the production and the value of the 10 principal crops for the years 1918 and 1923:—

| Commodities         | Area, hectares <sup>1</sup> |           | Production, metric tons <sup>2</sup> |                           | Value, pesos <sup>3</sup> |                      |
|---------------------|-----------------------------|-----------|--------------------------------------|---------------------------|---------------------------|----------------------|
|                     | 1923                        | 1918      | 1923                                 | 1918                      | 1923                      | 1918                 |
| Rice                | 1,675,870                   | 1,368,140 | 1,882,992                            | 1,539,187                 | 149,475,950               | 135,163,375          |
| Abacá (Manila hemp) | 513,420                     | 512,208   | 188,889                              | 166,864                   | 39,317,490                | 92,493,224           |
| Sugar-cane          | 227,290                     | 205,511   | 431,212                              | 430,686                   | 87,831,550                | 41,158,779           |
| Coconuts            | 456,440                     | 335,602   | 1,515,253,000<br>(number)            | 1,506,796,000<br>(number) | 64,366,220                | 56,533,793           |
| Tobacco             | 64,730                      | 78,443    | 32,806                               | 61,555                    | 6,814,800                 | 15,219,155           |
| Maize               | 557,690                     | 418,386   | 457,992                              | 309,799                   | 32,388,700                | 21,018,648           |
| Maguay              | 28,575                      | 32,601    | 27,033                               | 15,665                    | 3,018,770                 | 3,707,213            |
| Cacao               | 1,320                       | 1,142     | 1,030                                | 566                       | 1,145,500                 | 504,670              |
| Coffee              | 1,156                       | 768       | 1,328                                | 722                       | 787,300                   | 445,983 <sup>1</sup> |
| Sweet potatoes      | 80,350                      | 47,594    | 188,483                              | 313,068                   | 3,751,100                 | (not available)      |

<sup>1</sup> The hectare is equivalent to 2.47 acres.

<sup>2</sup> The metric ton is equivalent to 2,204.6 lb. avoirdupois.

<sup>3</sup> The peso is nominally equivalent to 50 cents in U.S. currency.

**Foreign Trade.**—The peak was reached in 1920, when the value of exports reached 302,248,712 pesos and of imports 299,676,566 pesos. This was due to war conditions and the feverish demand of the early reconstruction period, when high prices ruled. In 1921, the total value of the foreign trade fell below that of 1920 by almost 200,000,000 pesos. In 1923, with increased demand and better purchasing power, exports rose to 241,506,980 pesos and imports to 175,599,494 pesos. In 1924 the increase in both exports and imports persisted, the former being valued at 270,689,325 pesos and the latter at 216,021,790 pesos. In 1923, about 86% of the export trade consisted of coconut products, cane sugar, abacá and tobacco products, and for many years the proportion represented by these products had been something over 80%.

The principal countries of export are the United States, Japan and Great Britain. Exports to the United States rose from less than 16,000,000 pesos in 1900 to 194,500,000 pesos in 1924; to Japan, from 1,500,000 pesos in 1900 to 12,500,000 pesos in 1924; to Great Britain, from over 16,000,000 pesos in 1900 to about 18,800,000 pesos in 1924. Imports from the United States were valued at 4,300,000 pesos in 1900 and at 120,700,000 pesos in 1924; from Japan, at approximately 800,000 pesos in 1900 and at

17,000,000 pesos in 1924; from Great Britain, at approximately 11,100,000 pesos in 1900 and at over 9,500,000 pesos in 1924. Other exports (in the order of their importance in 1924) were to Spain, China, Germany, France, Hongkong, the Netherlands, Italy, Belgium, British East Indies and Australia. Other principal sources of imports were French East Indies (almost wholly rice), China, Dutch East Indies, Australia, Germany, Switzerland, British East Indies, France, Spain and Japanese China. Trade with the United States was given a great impetus by the Underwood Tariff Act of 1913, which abolished all duties between the two countries. The principal imports from the United States were machinery, construction materials, motorcars and accessories and cotton goods. Imports of agricultural machinery were especially important. The United States furnishes almost all the automobiles and trucks used in the islands. Cotton and manufactures thereof meet heavy competition from Great Britain. From China come many foodstuffs, and from Australia much of the wheat consumed and a good proportion of the meat. Trade with Japan has increased rapidly, while Great Britain has difficulty in maintaining its trade.

**Communications and Transportation.**—The good roads campaign, instituted almost at the beginning of the American occupation, has been one of the most important economic movements in the archipelago. The results are apparent in the better marketing methods made possible. There are two railway lines, one in the island of Luzon and the other in the islands of Panay and Cebu. The Luzon system, known as the Manila Railroad, is owned and controlled by the Government, but Gov.-Gen. Wood has recommended that it be sold or leased to a private company. The Manila Electric Co. (operated on a 50-year franchise and under the control of the J. G. White Management Corporation) has an extent of about 90 km. in Manila and the province of Rizal. It operates about 160 cars and carries about 33,500,000 passengers annually. The use of trucks and automobiles is increasing rapidly in all parts of the islands. In

1924 there were 914 post offices and over 500 municipalities with free delivery mail service. Mails are received three times weekly from China, twice weekly from Japan, once weekly from the United States, India, Java and the Straits Settlements and about fortnightly from Australia.

European mail is received and sent by way of the Suez Canal. It usually goes either way on an average of once weekly. In 1923 there were 397 telegraph stations (of which 24 were wireless stations) with 7,450 km. of line. The U.S. Army and Navy also had in operation seven wireless stations, one of which was open for commercial messages. Two cable lines ensure outside communication. In 1923 there were 14,122 telephones with 27,000 km. of wire. In 1899, 277 foreign vessels with a net tonnage of 322,130 entered harbour, and 273 ships with a net tonnage of 336,550 cleared for foreign ports. In 1923, 979 ships entered and 948 cleared, with net tonnage of 3,351,022 and 3,242,753 respectively. Manila is the chief port, but considerable shipping enters and clears through the minor ports of Cebu, Iloilo and Zamboanga, and smaller amounts through Jolo and Davao. In 1923, 230 steam and 730 sailing vessels were engaged in the inter-island trade. In all there are about 200 ports of call in the islands.

*Banking.*—By a charter granted on May 2 1916 by the Philippine legislature the Philippine National Bank was inaugurated, with an authorised capital of \$10,000,000, the Government subscription being \$5,050,000. The bank was made by law the depository of all Government funds by an Act of July 1 1916. A further legislative Act authorised the increase of capital to \$25,000,000, of which the Government subscription was \$12,700,000. The mint of the Philippine Islands has been established at Manila for the minting of Philippine coinage.

## II. HISTORY

*The Harrison Administration.*—W. Cameron Forbes, who was appointed governor-general on Nov. 11 1909, was replaced on Oct. 6 1913 by Francis Burton Harrison, as a consequence of the victory of the Democratic party in the United States with the election of Woodrow Wilson as President. Harrison held office for seven years, resigning after the election of President Harding. In his place, Gen. Leonard Wood was appointed governor-general in Oct. 1921, and was still in office in 1926. When Harrison took office, the Filipinos were given a majority on the Philippine Commission, the Upper House of the Legislature as then constituted, thus assuring Filipino control of both Houses. Interpreting most broadly his instructions, Harrison accelerated the Filipinisation of the civil service. The result was that, while undoubtedly the elimination of American employees was, in some few cases, justifiable because of lack of efficiency or because of incompatibility, the service of many Americans who had laboured enthusiastically and unselfishly was lost to the Philippines. An added incentive to Americans to leave government service, intended expressly for that purpose, was provided by the enactment in 1916 of a temporary pension Act applicable to employees who had been in the Philippine service for six or 10 years or longer. Petition for retirement under this Act had to be made by a specific date. The 2,623 Americans in the civil service in 1913 had shrunk to 760 in 1920, while Filipino employees during the same period had risen from 6,363 to 12,947. By the end of Dec. 1923 the numbers were 562 and 14,167 respectively; and of the Americans 329 were school teachers, while the remainder were mainly engineers in the bureau of public works and constabulary officers.

*Independence Movement.*—During the seven years of the Harrison administration, when Filipino autonomy was exercised to a greater degree than at any other period, various events and movements led critics to take a discouraging view of Filipino efficiency in, and capacity for, self-government. These critics pointed to the troubles of the bureau of lands, the inefficient reorganisation of the bureau of science, the breakdown in the health service, with disastrous outbreaks of smallpox and cholera and the increase in tuberculosis; the backward steps taken in the rinderpest campaign, the results of the government's entry into business, and the harmful political background and activities, as abundant proof of the necessity of continued guidance by the United States. Other Americans considered that the Filipinos had progressed far enough on the road toward self-government to manage their own affairs, and desired that the United States withdraw its sovereignty at once or as soon as possible.

The most important political movement since 1907—the year when the first Philippine Assembly (the Lower House) was convened—was the campaign for independence. This overshadowed all else, and the question was cleverly kept to the fore by the Filipino political leaders. Undoubtedly a majority of the people desired independence, some immediately, others eventually; some absolute, others conditional. Those not desiring independence, or who thought that it should come only after a long period, hesitated to make their views public. Perhaps the most general sentiment in the United States was for withdrawal at some future date unless the Filipinos themselves asked that American control persist.

One of the earliest acts of President Harding was the dispatch of the Wood-Forbes mission to the Philippines to make a thorough investigation and report of conditions. After an exhaustive investigation, which took them into nearly every part of

the archipelago, the heads of the mission submitted a comprehensive report advising that the time had not yet come to withdraw the sovereignty of the United States, and that the United States should not be left in a condition of responsibility without authority. It was in line with the findings of the report that the President appointed Gen. Leonard Wood governor-general to replace Francis Burton Harrison. Gen. Wood accepted the appointment, and immediately entered upon the thankless task of rebuilding American authority and prestige, which had been weakened by the preceding administration. In this, as might be expected, he met with the hostility of the political leaders, especially those of the *Nacionalista* party.

*Governorship of Gen. Wood.*—This hostility was apparent in various ways, and little effort was made to conceal it. General Wood's recommendations were shelved whenever possible; and complaints were made that he had surrounded himself with a "kitchen cabinet" and that he sought to govern by military methods. More serious opposition arose, however, in two cases. The first was Wood's reinstatement to office of an American detective, named Conley, who had long been connected with the police department in Manila; and the second was the veto of a bill enacted by the Philippine legislature remitting the penalty for the non-payment of the land tax. The Conley case was designated by the Filipino political leaders as an inroad by the governor-general on the prerogatives of the executive departments; and the veto as an unwarrantable meddling with purely domestic concerns over which the Jones Act gave the governor-general no power to veto.

With regard to Conley, the facts seem to be that because of his activities he had gained the ill-will of the gambling and criminal class, some of whom were able to exert considerable influence in certain quarters. Accusations of having accepted a bribe were brought against him, but several investigations made by the prosecuting attorney of Manila and the courts failed to disclose any official wrongdoing. The Secretary of the Interior demanded that a departmental investigation be made, but the governor-general refused and the investigation was carried on through the courts. Reinstatement being ordered, the secretary and then the mayor of Manila resigned. Accordingly, Wood reinstated Conley himself, and then accepted his resignation because it was found that he was guilty of an irregularity contrary to the rules of the civil service. With respect to the veto, the governor-general based his action on section 19 of the Jones Act, which outlines the procedure to be followed in all legislation enacted by the Philippine legislature.

The Filipino rejoinder to the reinstatement of Conley was the resignation on July 17 1923 of the President of the Philippine Senate and the Speaker of the House of Representatives as members of the Council of State, and of the departmental secretaries, with the exception of the Secretary of Public Instruction (who is also vice-governor, and, by law, an American), both as secretaries and as members of the Council of State. Wood, although surprised at the action, and regarding it as a challenge and a threat, accepted the resignations. On July 23 1923 the legislature, sitting as the commission of independence, ratified the action of the Filipino officials, and declared that it would defend the constitutional liberties of the Filipinos against the encroachments of the governor-general and keep inviolate the domestic autonomy already granted to the Filipinos, and upheld by the organic Act and the other laws in force in the country. The next day the same body declared that Wood should be recalled in the mutual interest of the Philippines and the United States. On Jan. 8, in a memorial to the Congress of the United States, presented by Manuel Roxas, Speaker of the House of Representatives, acting with the two resident commissioners, Isauro Gabaldon and Pedro Guevara, Wood was again charged with autocratic tendencies and with overriding Filipino rights. He was upheld by the Secretary of War and by President Coolidge, both in regard to his action in the Conley case and in the veto.

*Autonomy Missions to U.S.*—One of the features of the campaign for independence had been the sending of independence missions to the United States. Five of these missions had been

sent, namely in the years 1919, 1922, 1923, 1924 and 1925. The 1919 mission arrived while President Wilson was attending the peace negotiations in Paris. He sent a cordial message regretting his inability to receive the mission, with an assurance that the time seemed near for the realisation of Filipino hopes. The mission of 1922 was received by President Harding, who, while stating that he was not yet prepared to recommend the granting of independence, assured the mission that no backward step in the relations of Americans and Filipinos would be taken during his administration. The mission arriving in 1923 presented its memorial early in January. On Feb. 21, President Coolidge rather vigorously answered the mission, stating that inability to co-operate with Gov.-Gen. Wood, in view of the excellent administration he was giving, might be proof that Filipinos were unprepared for independent citizenship and that the time had not yet come for independence. The several missions, together with the independence propaganda and the influence of some Americans, both officials and private persons, were factors in the bills for greater autonomy or for the withdrawal of American sovereignty that were introduced into the first session of the 68th Congress. On these bills two extended hearings were held in the first half of 1924. None of the bills had become law by 1925; but they show the latest trend of legislation in the United States for the Philippines and point perhaps to even greater autonomy than is now enjoyed.

In May 1925 the Philippine Islands were received into the Inter-parliamentary Union, and the Filipino delegate to that union, Senator Osmeña, attended the 23rd convention of that body in Washington.

In the early part of 1926 news was received of the departure of an economic mission despatched to the Philippines by President Coolidge.

Because of the claim of the Netherlands Govt. to the island of Palmas, or Miangas, lying southeast of Mindanao, which has generally been regarded as part of the Philippine archipelago, the Netherlands and the United States agreed, on Jan. 23 1925, to settle the matter by arbitration. The case has been referred to the Permanent Court of Arbitration at The Hague, and the arbitral tribunal is to consist of a single arbiter. The United States has presented its first arguments which have been answered by the Netherlands government.

**PHILLIMORE, WALTER GEORGE FRANK PHILLIMORE**, 1ST BARON (1845– ), British judge, was born in London Nov. 21 1845, the eldest son of Sir Robert Joseph Phillimore, Bart. (see 21.405). Educated at Westminster School and Christ Church, Oxford, he won the Vinerian scholarship and was elected to an All Souls fellowship. He was called to the Bar in 1868. In 1885 he succeeded his father as second baronet, and in 1897 was made a judge of the Queen's Bench division, being in 1913 appointed a lord justice of appeal and sworn of the privy council. He retired from the bench in 1916, and in 1918 was raised to the peerage. He was from 1905 to 1908 president of the International Law Association. In 1918 he became chairman of the naval prize tribunal. Lord Phillimore was English representative on the commission which sat at The Hague in 1920 to prepare the scheme of a permanent Court of International Justice.

Lord Phillimore's publications include *Three Centuries of Treaties of Peace and Their Teaching* (1917); he also revised J. H. Blunt's *Book of Church Law* and several of his father's works.

**PHILLIPS, STEPHEN** (1868–1915), British poet (see 21.407), died at Deal, Kent, Dec. 9 1915.

**PHILOLOGY** (see 21.414).—Since 1910 there has been a remarkable revival of interest in linguistic science. A number of linguists have turned aside from their specialist activities and concerned themselves with the restatement of fundamental principles. Among these works may be mentioned Otto Jespersen, *Language, Its Nature, Development and Origin*, and *The Philosophy of Grammar*; J. Vendryes, *Le Langage, Introduction Linguistique à l'Histoire* and E. Sapir's *Language: an Introduction to the Study of Speech*. These writers approach the study of language from notably distinct viewpoints, so that their books supplement rather than parallel each other. Jespersen is mainly concerned with the more important modern languages of Europe and takes into consideration a good many matters of practical interest ordinarily neglected by the scientific linguist. Vendryes writes from the standpoint of the Indo-Europeanist and stresses the comparative and historical points of view. Sapir, a specialist in American Indian languages, is chiefly concerned with formal and psychological fundamentals, and uses freely examples taken from the languages of primitive peoples.

*Psychology.*—It is very noteworthy that other social and humanistic sciences than linguistics itself have taken a serious interest in the data of language. Psychology, which had been disposed to neglect language behaviour, has begun to analyse it more carefully in terms of stimulus and response; of habit; of adaptive function. A notable contribution to the understanding of language as a particular type of behaviour is J. R. Kantor's paper on *An Analysis of Psychological Language Data*, in which the peculiar characteristics of speech, whether communicative or expressive, are sought in its indirect nature as a response, the "adaptive stimulus" being responded to not directly but in the form of a reference, while a secondary stimulus, generally the person spoken to, is substitutively reacted to. J. B. Watson, the extreme exponent of behaviourism, sees in language merely a series of highly specialised laryngeal habits, and goes so far as to identify language with thinking by interpreting the latter type of behaviour as implicit or "sub-vocal" laryngeating. Such ultra-behaviouristic interpretations of language are not likely to meet with the approval of the linguists themselves, but they may have a certain value in accustoming us to approach the study of language habits without necessary reference to the logicians' world of "concepts." There is reason to believe that the kind of psychology (see **PSYCHOLOGY**) which will prove of the greatest value to linguistic science is the *Gestalt psychologie* (configurative psychology), which is still in its elementary stages. In this type of thinking the emphasis on behaviour is placed on the total form or configuration of a sequence of acts viewed as a system. To apply configurative psychology to language one may say that no linguistic act, however elementary, can be looked upon as a mere response, nor can even the simplest speech articulation be understood in terms of muscular and nervous adjustments alone.

Language always implies a particular kind of selective organisation: no speech sound, as Sapir has shown in a paper on *Sound Patterns in Language*, is intelligible as a habit without reference to the complete system of sounds characteristic of a given language, the individual sound being defined not merely as an articulation, but as a point in a pattern, with the other points of which it has intuitively felt relations (see **PHONETICS**). For the more complex levels of linguistic organisation the pattern point of view is more obviously in place.

*Philosophy.*—Even more fruitful for linguistics than psychology has been the work of certain philosophers. As the relativity of all knowledge and all experience to the habitual symbolism by means of which they are expressed has become more and more clearly understood, philosophy has begun to take a very lively interest in the relation between language and thought, in the nature of the symbolic process exemplified in, but not exhausted by, language, and in allied problems of meaning, reference and classification of experience. Philosophers of standing, such as Cassirer, Delafosse and Ogden and Richards,

have been occupying themselves with linguistic problems as never before. New viewpoints have been arrived at which are of capital interest for both philosophy and linguistics. In an important work entitled *The Meaning of Meaning* Ogden and Richards have carefully explored the nature of the symbolic and referential process involved in the use of language and have classified the concept of "meaning" itself. Many problems that have occupied the attention of philosophers and logicians are shown to be not essential problems but pseudo-problems that arise from the almost unavoidable temptation to read an absolute validity into linguistic terms that are really devoid of meaning when they are disconnected from a more or less arbitrarily defined context.

*Forms of Speech.*—The study of forms of speech that are very different from those that most of us are accustomed to—say English, French or Latin—discloses the possibility of markedly distinct analyses of experience where one might naively suppose that our customary analysis via speech is resident, as it were, in the nature of things. Categories that are carefully developed in one language are but weakly developed, or not at all, in another. Even the elements of sensible experience, whether conceived of as thing (say "tree"), quality (say "blue") or action (say "give"), are not necessarily taken as equivalent ranges of reference ("concepts") in different languages, but may be included in, or distributed among, respectively different ranges. It may even happen that what in one language is a definite experiential concept, with an unambiguous mode of reference to it, finds not even a partial expression in another, but is left entirely to the implications of a given context. Such a language may be said to have no "word" or other element for the "idea" in question, from which, however, it need not in the least follow that it is incapable of satisfactorily conveying the total psychic sequence ("thought") or unit of communication in which the "idea," in another language, figures as an essential element. Linguistic expressions of this kind are naturally of the greatest value for our conception of the nature of "reality" and of our symbolised attitude toward it, and certain philosophers have not been slow to turn to language for this reason.

That in the process of thought linguistic mechanisms play an important part is beyond doubt. Material rich in interest for the philosopher, the psychologist, the philologist and the sociologist is afforded by the modes of classification in use in various language families, such as classificatory prefixes and generic determinatives.

*Sociology and Anthropology.*—Sociologists and anthropologists too have interested themselves in linguistic phenomena as indispensable to an understanding of social behaviour. Especial mention may be made of B. Malinowski's speculations on the linguistic expression of primitive peoples. The value of language as a delimiter and index of social groups is being increasingly recognised by sociologists. One may wonder, indeed, if there is any set of social habits that is more cohesive or more disrupting than language habits. Not only has language been an object of study in its own right, but it has shown itself increasingly to be of the greatest instrumental value in all historical studies. The best kind of ethnological and folkloristic material is that which is secured in the form of native texts, for material of this kind is not open to the charge of misrepresentation of the native point of view. Accordingly, we find that the text method of studying the cultures of exotic peoples, whether lettered or not, has been growing in favour, in spite of the obvious difficulties of the method, implying as it does a preliminary study of the exotic language itself. Indeed, much of the most competent and authoritative ethnological information that we possess has been obtained as material ancillary to linguistic studies. One may instance, for America, the Kwakiutl publications of Franz Boas and, for Africa, the Shilluk texts of D. Westermann.

*Place Names.*—In another sense, too, linguistic researches have been of great assistance, and that is in enabling us to make inferences as to the history and prehistory of various peoples. The value of place names, e.g., in the study of the former distributions of the various ethnic elements that go to make up the

present population of England, is well understood (see FOLKLORE). Much of the prehistory of Europe and Western Asia is being rewritten with the aid of a profounder study of place names. The non-Hellenic character of hundreds of well-known Greek place names, such as Athenai, Korinthos and Tiryns, is interesting and important in connection with our rapidly increasing knowledge of the pre-Hellenic or Minoan civilisation of the Aegean and of the mainland of Greece. The Etruscan problem, too, has been furthered by a study of the recorded place and personal names of Etruria that are clearly not of Italic origin. These show so many resemblances to names recorded from western Asia Minor (e.g., Lydia, Lycia) that there is now less hesitation than before to credit the testimony of Herodotus, who derives the Turrhenoi (Etrusci) from Asia Minor.

*General Tendencies.*—We may point out a number of tendencies in recent linguistic thinking. First of all, there is a growing realisation that the life of language is similar in all parts of the world, regardless of the race or cultural development of the speakers of the language, and that the rate of linguistic change is not seriously dependent on the presence or absence of writing. The supposed conservative power of a system of writing, it is now generally agreed, is altogether mythical. It is an illusion to imagine, for instance, that Chinese as a spoken language was hindered from the normal rate of change because of an early literary fixation. Not only have the modern dialects a notably different vocabulary from classical Chinese but their pronunciation has been so modified that it is clear that present-day Mandarin or Cantonese would be quite as unintelligible to Confucius as present-day Spanish to Cicero.

*Internal Factors in Change.*—The most important single factor making for an increased or retarded rate of linguistic change would seem to be the formal set of the language itself. It is significant, for instance, that the Semitic languages have changed very much less in the last 3,000 years than have the Indo-European languages. The Athabaskan (Déné) languages of North America, spoken by unlettered tribes which had, for the most part, reached but a very primitive level of culture, have tended to resist morphological change because of a certain formal equilibrium, despite the complexity of their grammatical structure, hence such widely separated languages as Navaho (New Mexico and Arizona), Hupa (Northern California) and Chipewyan (Mackenzie Valley) differ probably less than French and Italian (see ARCHAEOLOGY: CENTRAL AMERICA).

*Consistency of Change.*—One of the most impressive things about linguistic change within a given genetic group is the relative consistency of its direction over a long period of time. Well-known examples of this principle are the progressive simplification of the case system in all branches of the Indo-European family and the ever-increasing tendency to isolation in the structure of the Sinitic (Indo-Chinese) languages. It is very remarkable, too, that in many cases it can be shown that related languages have undergone similar developments independently of each other and at very different periods. "Umlaut," for instance, seems to have developed independently in West Germanic and in Scandinavian, just as certain tonal developments in modern Tibetan (central dialects) are significantly parallel to the far older tonal developments of the earliest Chinese. It is difficult to explain these parallelisms except on the assumption that a given formal set implies a certain liability to modification in one rather than in another direction.

*External Contacts.*—Important, yet less important than the inner "drift" of a language, is the tendency to change as a result of external contact. Not only lexical, but also far-reaching phonetic influences may be ascribed to the contact of unrelated languages. Although Annamite seems to be basically a Mon-Khmer language, therefore originally toneless, it has acquired a complicated tone mechanism which is, in principle, identical with that of the neighbouring Tai languages (Siamese, Shan, Laos, Thô). Morphological features, too, may be freely diffused, though the evidence for this is less convincing in most cases than for the spread of words and of phonetic elements and tendencies. Often it is difficult to say whether a morphological

parallelism is due to historic contact or to genetic relationship or to independent development.

The effects of bilingualism deserve attention, especially in those areas where permanent contact is established between two different families of speech, as in India, where Indo-Aryan languages are spoken in addition to Dravidian or Austric or Indo-Chinese tongues. The principles of the growth of *linguae francae* have also been examined, but much yet remains to be done. Internal social developments as well as exterior relations induce linguistic features of interest and of philological value in themselves. The phenomena recorded by anthropologists of secret speech, of slang, of special modes of speech associated with social divisions, women, age-grades, priests and kings bear witness to the importance and validity of linguistics in the study of social aggregates and their corporate manifestations.

*Morphology.*—The morphological classification of languages still leaves much to be desired. It is abundantly clear that the traditional classification of types of speech into isolating, agglutinative, inflective and polysynthetic is imperfect. It is difficult to find easily applicable criteria of general linguistic structure. Perhaps the safest plan is to adopt a number of distinct points of view and to classify a given language from each of these. Sapir suggests the possibility of three independent types of classification, based respectively on degree of synthesis, on the predominant "technique" (manner and degree of welding of elements into unities), and on the conceptual expressions. From the first point of view languages may be described as analytic (Chinese, Ewe), weakly synthetic (English, Tibetan), synthetic (Latin, Turkish, Japanese) and polysynthetic (Eskimo, Algonquin). The classification based on "technique" is into isolating (Chinese, Annamite), agglutinative (Turkish, Nootka, Bantu), fusional (Latin, French, Yokuts) and "symbolic," *i.e.*, with the characteristic employment of various types of internal change, such as vocalic and consonantal change, reduplication and differences of stress and pitch (Semitic, Shilluk). A conceptual classification would distinguish between languages which can and those which cannot freely derive words from basic elements and, further, between those which express the fundamental relational (syntactic) concepts as such and those which need adventitious concepts like gender or number to bring out these necessary relational ideas. There would, therefore, be theoretically four conceptual types of languages—pure-relational, non-deriving languages (Chinese), pure-relational deriving languages (Polynesian, Haida), mixed-relational non-deriving languages (but meagrely represented) and mixed-relational deriving languages (Latin, Semitic, Algonkin).

*Phonetics.*—Much progress has been made in phonetic research (see PHONETICS). A vast number of new sounds have been discovered and whole classes of articulation come to light from time to time whose existence could not readily have been foretold by an *a priori* phonetic analysis. The help derived by linguists from objective methods of investigation (various types of recording apparatus) has been welcome but, none the less, disappointing on the whole. A well-trained ear can readily make and classify sound differences which a kymograph does not materially help us to understand. As our knowledge of phonetics grows, we realise that sounds and phonetic discriminations originally believed to have a quite restricted distribution are really rather widely distributed. The Hottentot and Bushman clicks, partly borrowed by certain Bantu languages, seem to be confined to South Africa. But the curious glottalised consonants and voiceless laterals of Western American languages are found as well in the Caucasus and in a number of African languages. Again, tone differences or significant elements in the word are by no means confined to Chinese and related languages in Eastern Asia. We now know that pitch languages are exceedingly common. Most of the African languages that are not Semitic or Hamitic are pitch languages (Sudanese, Bantu, Hottentot, Bushman), while in aboriginal America a very considerable number of languages have been found to recognise tonal differences (*e.g.*, Athabaskan, Tlingit, Achomawi, Takelma, Tewa, Mohave, Mixtecapotec, Chinantec, Otomi and many others).

*Genetic Relations.*—For a long time linguists hesitated to look for genetic connections between the groups and isolated languages that had been established. There is an increasing tendency now to make larger syntheses and to suggest as at least probable, if not entirely demonstrable, relations that at first blush seem far-fetched. Among serious linguists Alfredo Trombetti is perhaps the only one who has ventured to commit himself to the theory of linguistic monogenesis and has actually attempted (see his *Elementi di Glottologia*) to show in what manner the various groups of languages that are generally recognised are related to each other. The most important general survey of languages published in recent years, *Les Langues du Monde*, edited by A. Meillet and Marcel Cohen, is very conservative in the matter of genetic theories, but even in this a number of syntheses are allowed that would not have passed muster a few decades ago. There is no doubt that as our comparative knowledge becomes more profound we shall be enabled to extend our genetic groups with safety.

*North and South American Languages.*—We can only glance at some of the new genetic theories. The incredibly complicated linguistic picture of North and South America, which has long been proverbial among linguists is likely to become very appreciably simplified. R. B. Dixon, A. L. Kroeber, P. Radin, Sapir, G. R. Swanton and P. Rivet are among those who have sought to bring order out of the linguistic chaos that still largely prevails in America. For the groups of languages spoken north of Mexico and in part in Mexico Sapir suggests a greatly simplified classification into six genetic groups, Eskimo, Nadene (Haida, Tlingit-Athabaskan), Hokan-Siouan, Algonquin-Wakashan, Penutian and Aztek-Tanoan. These groups, aside from Eskimo, embrace languages, however, which differ vastly more than the Indo-European languages. In South America Rivet has connected various groups of languages hitherto believed to be unrelated. He has also attempted to prove a relationship between certain Fuegian languages and the languages of Australia, and between the Hokan languages of California and Polynesian.

*The Austric and Australian Languages.*—More likely to prove sound than these latter theories is Father W. Schmidt's linguistic synthesis which passes under the name of "Austric" and which includes the vast group of languages—Mon-Khmer (Mon-Khmer proper; Khasi; Proto-Malaccan, Nicobarese; Munda) and Malayo-Polynesian.

Analysis of the Australian languages by Father Schmidt seems to disclose the existence of a definite distinction between the northern and southern groups. The northern group is resolved into two main divisions with a third division of an intermediate nature. There are marked differences in the southern group, some of which are regarded as approaching Tasmanian (now extinct) and as therefore markedly primitive. To a very large extent linguistic differences in this area, claims Father Schmidt, can be correlated with, variations of, or differences in, other cultural features such as social organisation.<sup>1</sup>

*African Languages.*—In Africa we may note as important the discovery of a language spoken in the east-central portion of the continent: Sandawe, which is unmistakably related to Hottentot, spoken far to the south. This lends an unexpected colour to theories long prevalent as to the Hamitic affiliation of Hottentot. The sharp line of demarcation which used to be drawn between the Bantu and Sudanese languages is giving way. Everything points to the fact that the Sudanese languages are a worn-down form of a language, or group of languages, which was genetically related to Bantu. A number of Sudanese languages possess class prefixes (or suffixes) that are strongly reminiscent of the Bantu prefixes, while bare survivals of these elements persist in a great many other Sudanese languages.

The publication of Sir H. H. Johnston's work on the Bantu languages was an event of first class scientific importance. It summarises and surveys with masterly power the sweep of this family of languages throughout Africa and argues that "the Bantu family was finally moulded by some non-negro incomers of

<sup>1</sup>*Anthropos*, vol. 8 (1912), p. 260 and p. 463; vol. 9 (1913), p. 526.

possibly Hamitic affinities, akin at any rate in physique and culture, if not in language, to the dynastic Egyptians, the Gallas and perhaps most of all to those 'Ethiopians' of mixed Egyptian and Negro-Nubian stock that, down to 1,000 years ago, inhabited the Nile basin south of Wadi-Halfa and north of Kordofan."

*Indo-European, Semitic and Hamitic Languages.*—Hermann Möllers' very systematic and detailed attempt to connect Indo-European and Semitic (the relationship of which to Hamitic is now generally recognised) seems not to have been cordially received by either the Indo-Europeanists or the Semitists, but to the general linguist who studies his works his demonstration seems highly suggestive, not to say convincing. Less solid seems to be the attempt of N. Marr, a Russian linguist, to establish a "zaphetic" group of languages, consisting of the Caucasian languages, Basque, and that large number of still very imperfectly known languages which preceded the Indo-European group in southern Europe and western Asia (Etruscan, Minoan, "Asianic" [early Hittite]).

More and more it is becoming evident that the linguistic cartography of the Near East and of Europe was a complicated one in remote times. The discovery and partial decipherment of a series of cuneiform "Hittite" inscriptions from the second millennium B.C. proves a number of interesting things—that a language closely related to Sanskrit and known from quoted terms was spoken in the neighbourhood of the Hittite country; that the language of the Hittite rulers had unmistakable Indo-European features, but was not typically, or even mainly, Indo-European in character; and that an older Hittite language was quite unrelated to this. Just what relationship, if any, the non-Indo-European elements of these Hittite languages bear to "Asianic" (Lycian, Lydian, Carian and others) and the Caucasian, remains to be discovered (see *ARCHAEOLOGY: WESTERN ASIA*).

*Discovery of Tokharian.*—Perhaps the most interesting linguistic discovery\* that has been made of recent years in the domain of Indo-European philology, apart from the "pseudo-Hittite" documents just referred to, is the presence of two dialects of a language, generally termed Tokharian in Chinese Turkistan, as late as the 7th century A.D. Tokharian is quite distinct from any other known Indo-European language and has thrown light on a number of points of Indo-European grammar. In certain phonetic respects it agrees more closely with Greek and Latin than with the Indo-Iranian languages that were geographically nearer to it.

*Pisacha Languages.*—Problems of an interesting nature are raised by the evidence published (1919) in vol. 8, part 2, of the *Linguistic Survey of India* by Sir George Grierson, who describes the Dardic or Pisacha languages as not possessing all the characteristics either of Indo-Aryan or of Eranian. They exhibit almost unaltered and in common use words which in India are hardly found except in Vedic Sanskrit. The wild, mountainous country in which these languages are found has not attracted the conqueror. An interesting feature is the survival of words from Burushaski, a form of speech which has not yet been satisfactorily related to any other language group.

*Karen Languages.*—Examination of the languages spoken in Burma, an area not covered by the *Linguistic Survey*, has justified the view that the Karen group of languages constitute a new family of languages which exhibits features resembling those of the Chin and Sak languages, even of some of the sub-Himalayan dialects. Sir George Grierson suggests the possibility of a widespread pre-Tibeto-Burman population, which was absorbed, with parts of its language, by the later Tibeto-Burman immigrants.

*Other Families.*—The Man family is similarly regarded as distinct but it is a newcomer from Southern China, whence further evidence may be available to identify its main relationship. There are thus in the confines of the Indian Empire language stocks of world-wide distribution and languages—the Dravidian tongues—Burushaski, Karen, Man and Andamanese, which survive in isolation. It has been surmised that Dravidian languages may be related to Sumerian or to Basque, or to a common prototype, but

conclusive evidence has not yet been put forward in proof of these hypotheses.

Vendryes, *Le Langage* (1921); E. Sapir, *Language* (1921); C. K. Ogden and I. A. Richards, *The Meaning of Meaning* (1923); O. Jespersen, *Language, its Nature, Development, and Origin* (1922); Sir G. A. Grierson, *Linguistic Survey of India*, vol. 8-11 (1919-22); *India Census Report* (1921). (E. SR.)

**PHILOSOPHY** (see 21.440).—Philosophy is the branch of knowledge which aims at ascertaining the ultimate character of reality. In this it differs from science, which, observing and experimenting within the field of experience, seeks to exhibit the results so ascertained in the form of general principles. Science investigates the structure of experience, but does not, broadly speaking, try to get behind it. Philosophy, so far as its metaphysical aspect is concerned, asks what experience means and what are its foundations. The distinction has been made more sharp by the emergence of the theory of knowledge which inquires what is signified by being *for* mind, as contrasted with the object world being assumed to be self-subsistent, without reference to any function of knowledge in its constitution. The latter is the subject of ontology. The former claims that ontology is no more than a branch to be included properly as a phase in the wider theory of knowledge which is sometimes called epistemology.

The emergence of the theory of knowledge as such has become definite as metaphysics has been developed. This development culminated in the teaching of Kant at the end of the 18th century. Kant insisted that, when its true nature was ascertained, knowledge must be recognised—firstly, as more than a property of the individual self which we find in the object world of experience; secondly, as having its foundations in a synthetic unity of activity which, as the condition under which alone experience was possible, could never be presented as an object within it; and, thirdly, as the activity of thought, identical in all individuals, because foundational of both their experience and themselves, which must be recognised if we were to hope to account for an objective universe identical and one and the same for all individuals. These individuals were objects in experience, as well as subjects in knowledge, and as such objects were moulded by their stations and conditions in nature. But they were in their more general character the manifestation of the synthetic activity which, as the foundation of mind and perception, was present in all of them.

*Earlier Systems.*—The sharp distinction, made by Kant for the first time clearly, was not equally apparent in the old Indian or Greek philosophy. In the earlier philosophies men were less troubled by the difference supposed to exist between knowing and being. The great systems of Indian philosophy show little consciousness of this, which has been the prominent difficulty for modern and Western metaphysics. This is not altogether to the discredit of the older systems. Indian and Greek thought as we find the latter in Plato and Aristotle and in Plotinus, are almost equally free from the perplexity that has been caused by an undue insistence on that divergence of knowing from being which modern metaphysics has made prominent. Indeed, even Descartes, Spinoza and Leibnitz were hardly more troubled over this divergence than were their predecessors in the older metaphysics.

*Kant's Position.*—But the psychological tendency of modern times, and the constant turning to experience, made the problem more acute. How could the mind, as an object in experience, be regarded as creative of its object world? This was the problem to which the philosophy of Kant addressed itself, and he solved it by making the distinction above indicated between the two aspects of mind, as an object in nature and as, at the same time, inherently creative. For him mind created its objects by operating under the forms of space and time on a raw and unformed material, and such as the senses might in themselves afford, and shaping it in the process into a formed world. It might be that the ultimate source of this raw material was mind itself in its initial aspect, or it might be that the raw material was

supplied *aliunde*. Into this question Kant declined to enter. The structure of experience was such that the question could not be solved.

*Hegel and Others.*—After the time of Kant great divergence of view became apparent on this problem. Schopenhauer, early in the last century, found in Will the explanation of Kant's "thing in itself" and the source not only of mind but of the raw material. Bergson, later on, found that source in his "*durée*," time not yet spatialised, which was the ultimate form of reality, an activity which lay deeper down than either mind or its objects. But in the early part of the 19th century, the doctrine of Kant was expanded in a wholly different direction. It was held that Kant had taken a view too narrow of the nature of knowledge, even as he had stated it in the principle of its foundational synthetic unity. For Fichte, Schelling and Hegel knowledge meant and covered much more. It was not by them confined by Kant's list of categories deduced from the abstract principles of the judgments of formal logic.

In Hegel, especially, the start was made from our experience, and knowledge was treated as foundational to the whole of this and as including even the distinctions made within feeling and volition. It is not surprising that, in an age when nothing was deemed to have been sufficiently worked out unless it could be exhibited in the form of a complete system, the ideal of knowledge thus arrived at should have been sought to be exhibited as a system of an absolute kind, in which God and all forms of apparent externality to thought not less should be displayed in a fully systematised and detailed form as the substance of an entirety in which knowledge as foundational was what could not be transcended. Such a conclusion was of course a great advance on that of the cautious Kant, but it accorded with the tendencies of what Kant had taught.

*The Absolute.*—After Hegel's time the doctrine of the absolute so conceived passed out of fashion in Germany, but in other forms it was taken up in Great Britain by such teachers as T. H. Green and Edward Caird, who gave it a restricted shape but one which was still in substance Hegelian. They were succeeded as leaders of thought by F. H. Bradley and Bernard Bosanquet, but these struck out a different conclusion. There was for them an absolute, but the form of knowledge, always relational, was insufficient for its rendering. There was an alternative form in which they themselves sought to render it, that of a kind of knowledge in which relational thought and bare feeling were both transcended, and which culminated logically in an absolute of a new kind within which both fell. Their teaching, issuing as it did in fresh doctrines of logic and psychology, exercised much influence, but did not create any large or definite school of adherents. In the United States the German doctrine of absolute idealism was taken up by such writers as Royce and Creighton, but its progress was deflected by the seminal teaching of William James and others, who ceased to rely on thought as the exclusive instrument, and called people back to the function of feeling in constituting experience. On this basis Pragmatism and New Realism—which does not shrink from finding in the objects of our experiences the presence even of universals—have made much progress, especially in America.

#### MODERN DEVELOPMENTS

The outcome of these somewhat divergent movements is that it is difficult to lay down generally the position of philosophy to-day. There is no single tendency to be found in it, and all that is clear is that psychology is receiving much more attention than it did in the 19th century. On the other hand, the influence of objective idealism is still strong, and there is perhaps less of a tendency to throw it into antithesis to psychological work than was formerly the case.

The influence of the new developments of physical science which are characteristic of the present century are exercising much influence, but, so far as can be seen, an influence which is not destructive of the new point of view which has grown out of Kant's teaching as to the importance of the part played by knowledge in the constitution of experience. In Germany itself this is also the

case. Writers like Cassirer and Husserl lay stress on it, and there appears to be a diminishing interest in the alternative special departure from Kant which Schopenhauer founded, and to which Bergson has given a new development in a different shape. Herbart, Lotze, Vaihinger, Mach, Riehl, Avenarius, Lange and others in Central Europe, show a tendency to recur to actual experience, and to treat the ideals which are sought for its foundations as belonging to a region of working hypotheses, but hypotheses merely. The impulse has often been toward the identification of truth with mental occurrences, what is sometimes called psychologism. "Back to Kant" means the repudiation of the effort to connect the ideals of Kant's successors with what we actually find in our experience.

In Great Britain it is more difficult to sum up the position definitely. There is still a great deal of the idealism, in the wider sense of the word, which refuses to be content with that to which Kant restricted himself. To call British idealism Hegelian would be wrong, for there is little interest in what Hegel felt himself bound to, the construction of a theory of the nature of what is absolute. Bradley was the last writer to lay stress on such a necessity. Still there is a good deal of writing in which the positivism of Kant has been laid aside. On the other hand, there is probably a large number of British students of philosophy who have wholly rejected the mandate of idealism as such, and have deliberately elected to confine themselves to the investigation of the structure of actual human experience. This problem is not the same problem as the other, but, in restricting themselves, these thinkers (and the same thing is true of thinkers in the United States and France) have taken the view that the apparently certain results which the progress of science and especially of psychology afford are giving them fresh ground on which to build up epistemology. In logic as well as in psychology this tendency is apparent.

It is not possible to forecast the future. So much work is being done, and so many fresh views are being brought forward, that the only thing that is certain is that modern movements, especially in this country, are not likely to stand still or to remain where they are. Not only science but literature also is reacting on philosophy, and the future will not disclose what are still its secrets.

*Philosophy and Ethics.*—The development of the ethical side of philosophy has naturally been profoundly influenced by the changes on the metaphysical side. The early moral philosophy of India was closely bound up with the religious outlook. The attempt to penetrate to the character of the ultimately real carried with it the sense of the obligation to renounce external goods and not less the interests of the individual self. The principle of renunciation in this way came to be the basis of Indian ethical thought in various forms. In ancient Greece, great as was the influence of Plato, the most distinctive and influential teaching of ethics was that of Aristotle. His influence has endured through the Middle Ages right down to our own times. He directed his investigation of the principles which regulate human conduct to the chief good. This he found to consist, not in pleasure, but in happiness. This is the activity of the highest part of man's nature. It is the activity of reason, which is the highest human faculty aiming at no end beyond itself. It bids us seek, not extremes, but the mean as that in which the self at its best can be active undisturbed. Aristotle worked out his ethical system from a survey of human nature in all its practical forms.

Kant, however, reshaped this conception. For him the determining motive power was to be sought in ideals, ideals which could never be presented as phases in actual human experience, but which moulded it. The conceptions of God, of freedom, and of immortality were for Kant of this order, and they were the foundations of ethical obligation. This sharp separation of knowledge from the content of experience led him to formulate the rule for conduct in a somewhat abstract form, the obligation to act always on maxims which applied universally and without reference to particular circumstances. His successors, and particularly Fichte and Hegel, found this, as we should expect from

their metaphysical tendencies, too abstract as a guide for humanity. They introduced the conception, intermediate between that of positive law on the one hand and of pure ideals on the other, of "Sittlichkeit," the obligation inspired by society in its members of what may be called "good form" or the "right thing to do." This new idea has exercised great influence in various forms. It is nearer to what Aristotle taught than to the doctrine of Kant. It has enabled moralists to avoid the narrowness of utilitarianism on the one hand and of pure idealism on the other, and it has imparted a new significance to society as an ethical influence. The ethical philosophy of to-day is of very varied orders. But prominent throughout is the idea of values as a basis for morals. That quality should be unchallengeable as a guide to conduct is no new notion, but it is one that in a variety of forms has gained increasing importance in recent ethics.

*French and Italian Developments.*—In an article confined to prominent features in the history of philosophy it is not practicable to follow out the secondary developments of the history of thought. Such developments have importance both in France and in Italy. In France there were three influences, which led to corresponding schools. There was that of the physicists and physiologists initiated by Cabanis and continued by Pinel and a group of Paris physicians.

Then there was a psychological school in which Maine de Biran, writing in the beginning of the 19th century, was a pioneer. This school insists through him that we have immediate experience of the self and of a not-self. On this experience a metaphysical system is built based on a direct awareness, such as Bergson a century later set up as the foundation of his *durée*. In course of time the school founded by Maine de Biran came under the influence of the Scottish spirit in philosophy, that of Reid and Dugald Stewart, who had broken away from the principles of Kant. Cousin was the most prominent of this French section. Comte exercised much influence of a scientific tendency, and, after an interval, the school of Bergson attained to great prominence not only in France but outside it. In Italy the movement has been in the direction of an intellectualist idealism. The influence of Hegelianism is marked, but in the hands of thinkers like Croce and Gentile the doctrine has assumed a form of its own. See AESTHETICS; ANTHROPOLOGY; BIOLOGY; ETHICS; LOGIC; PSYCHOLOGY; SCEPTICISM; etc.

**PHONETICS** (see 21.458).—Considerable developments have taken place in phonetic science since 1910. The nature of many known speech-sounds has been determined with greater accuracy than before; attention has been given to features of pronunciation previously barely touched upon (notably intonation and

the theory of phonemes); many new languages have been subjected to phonetic analysis; new methods of teaching pronunciation have been evolved, and the use of phonetic methods in practical language teaching has been greatly extended.

*The Organic-Acoustic Method.*—The most useful practical method of determining the formation of speech-sounds is still the "organic-acoustic" method, i.e., estimating the position of the tongue by muscular sensation and by comparison of the acoustic quality of the sound to be analysed with that of other sounds of known tongue positions. This method has been supplemented by experimental methods (the use of apparatus, such as the phonetic kymograph, artificial palates and X-ray photography). For illustrations of the use of the kymograph and artificial palates see D. Jones's *Outline of English Phonetics* (1918 and 1922). X-ray photography was adopted first by E. A. Meyer as long ago as 1905,<sup>1</sup> and has been followed by other

FIG. 1.—Graphic representation of tongue positions of vowels. FIG. 2.—Tongue positions of i, e, ε, a. FIG. 3.—Tongue positions of a, o, u. FIG. 4.—Diagram illustrating the nature of the vowels of Italian, by reference to the cardinal vowels. (Cardinal vowels shown by black dots; Italian vowels by circles.)

investigators. Particularly noteworthy are the X-ray photographs taken of the mouths of Daniel Jones and Stephen Jones by Dr. H. Trevelyan George<sup>2</sup> and a remarkably good set of 30 skiagrams of the mouth of Stephen Jones taken by H. A. Harris and F. Melville in the Department of Physiology, University College, London, in 1925 (not yet published). E. A. Meyer has also obtained valuable results from an ingenious adaptation of the artificial palate.<sup>3</sup>

The relative tongue-positions of vowels may be indicated graphically by dots placed on a figure of the shape shown in fig. 1. Figs. 2 and 3 show the reasons for this. The upper curve from i to u in fig. 1 is parallel to the roof of the mouth; the descending part, u-a, indicates the limit of possible vowel-positions of the tongue in the backward direction. The descending part, i-a, of the lower curve indicates the limit of possible vowel-positions of the tongue in the forward direction, while the part, a-a, which is nearly horizontal, represents the lowest positions which the tongue can take up. The highest part of the tongue in pronouncing any vowel may be represented

<sup>1</sup> See article by him in *Medizinisch-pädagogische Monatsschrift für Sprachheilkunde*, Nos. 8, 9 (1907).

<sup>2</sup> Some of these are reproduced in *Proc. Royal Institution* (1919).

<sup>3</sup> See his "Untersuchungen über Lautbildung" in *Festschrift W. Viëtor* (Marburg, 1910), and "Beiträge zur Schwedischen Phonetik" in *Vox*, Part I (1916).

by means of a dot placed at the appropriate spot on the circumference or in the interior of this diagram.

In practical language teaching, this diagram is generally replaced by one of the shape shown in fig. 4. The introduction of angles serves to render the placing of the dots more definite and intelligible to ordinary learners, and facilitates the demarcation of a series of vowels known as "central" vowels, which are represented by dots placed within the inner triangle shown in fig. 4. This vowel figure, though being by no means mathematically accurate, is more accurate than its predecessors, the triangular arrangement (adopted by Viëtor and others), the square (Bell and Sweet) and the form  (Passy).

The quality of vowel sounds is dependent upon other factors besides the tongue-position. Foremost among these are the positions of the lips, which are now generally classified as "spread" (as for [i]), "neutral" (as for [a]), "open rounded" (as for [ɔ]) and "close rounded" (as for [u]). Some writers still use Sweet's further classification, based on the muscular condition of the tongue, into "narrow" ("tense") and "wide" ("slack," "lax") vowels. Others, however, now consider it better to classify according to the width of the pharyngeal passage, as this can be more satisfactorily measured than can the degree of tenseness or laxness of the tongue muscles. Thus [i] (as in *eat*) has a wide pharynx; [æ] (as in *cab*) has a narrow pharynx.

*The Cardinal Vowels.*—One of the most important modern developments of phonetics has been the establishing of a system of "cardinal vowels" as a standard of vowel-quality. By reference to eight vowels which have been carefully chosen, it is possible to describe the vowel-sounds of any language more accurately than before. Their relations to each other are shown by the black dots in fig. 4; it is taken as a convention that Nos. 7 and 8 have close lip-rounding, and that No. 6 has open lip-rounding. The old plan of describing vowels by key-words from existing languages has been discarded, since key-words are pronounced in a variety of ways by different speakers.

The eight primary cardinal vowels were selected as follows: The vowel sound produced with the front of the tongue raised as high as possible towards the hard palate is chosen as cardinal vowel No. 1. It is represented by the symbol [i]. All the i-like sounds occurring in any language or dialect (e.g., the different varieties of English [i] in *eat*, French [i] in *vite*, Hindustani [i] in *bhī*) can be described by reference to this fixed vowel position and the description understood by any reader knowing the value of cardinal vowel No. 1. The vowel sound produced with the tongue held as low and as far back as possible is cardinal vowel No. 5, the symbol for which is [a]. English [a] as in *calm*, French [a] in *pas*, Swedish [a] in *glad*, have values not far removed from cardinal [a], and may be accurately described by reference to it. The cardinal vowels Nos. 2, 3 and 4, represented by the symbols [e], [ɛ], [ə], were chosen so that the distances between successive pairs of cardinal vowels are, from the acoustic point of view, as equal as a highly trained ear can estimate. Nos. 6, 7 and 8 [ɔ], [o], [u], are "back" vowels so chosen as to form a continuation of the acoustic series [i, e, ɛ, a, d].

A set of secondary cardinal vowels (phonetically [y, ø, œ, ɐ, ɤ, ʌ, ʊ, ɯ]) is derived from the primary cardinal vowels by adding lip-rounding to [i, e, ɛ, a, d] and unrounding [ɔ, o, u]. There are also some "central" vowels, of which the chief are [ɨ] (intermediate between [i] and [u]), [ɜ] (intermediate between [y] and [u]), [ɘ] (the "neutral" vowel) and [ə] (variety of the vowel in *bird*).

The cardinal vowels can only be learnt from a teacher who knows them, or, failing that, from a gramophone record.<sup>2</sup> By means of dots placed on the cardinal vowel chart, together with instructions as to lip positions, anyone familiar with the cardinal vowels can form a good idea of the acoustic effects of foreign vowels, even if he has never heard them pronounced by a

native. Thus fig. 4 shows the nature of the vowels of Italian (shown by circles).

*Phonemes.*—Another development of far-reaching importance has been the elaboration of the theory of "phonemes," which has placed the distinction between a "broad" and "narrow" transcription on a firmer basis. The speech sounds (phones) existing in any one language are much more numerous than the average native speaker of that language imagines. They can be grouped into families technically called "phonemes." Each phoneme contains the most frequently used member of that family and a number of subsidiary members which take its place in certain positions in connected speech. For example, the sound of [h] in *hoop* is not the same speech-sound as that in *he* or in *half*. These and other varieties of [h] occurring in English belong to the English "h-phoneme." In Japanese, the h-phoneme includes such very different sounds as a voiceless palatal fricative [ç] (used before [i]) and a voiceless bilabial fricative [ɸ] (used before [u]). In the speech of most English people, the initial [l] in *little* ("clear" l) is not the same sound as the final [l] ("dark" l). These two l-sounds, and others with varying degrees of "clearness" and "darkness," belong to the English l-phoneme; the particular variety to be used in any given word or phrase depends upon the nature of the surrounding sounds. The a-phonemes in Russian and in Arabic contain members differing very widely from each other; the Arabic a-phoneme includes vowel-sounds ranging from a sound near to [æ] (as in *man*) to [ɐ] (as in *not*) and [ʌ] (as in *cup*), the character of neighbouring consonant sounds being responsible for these variations. In French the l-phoneme includes a voiceless [l̥] which is used when such words as *oncle*, *simple* occur finally.

In connected speech the use of the chief members of phonemes alone would never cause misunderstanding, for they are sufficient to distinguish the meanings of words; the proper use of the subsidiary members, though not essential for intelligibility, is nevertheless necessary if one wishes to speak a foreign language "like a native."

Two different speech-sounds may be members of the same phoneme in one language but belong to different phonemes in another language. Thus in Welsh and Zulu there exists a variety of voiceless [t̥] (represented by *h* in Welsh, *hl* in Zulu); this sound is a separate phoneme from [t] in these languages, contrary to the usage in French. [d] (as in *psalm*) and [æ] (as in *Sam*) are separate phonemes in English, but they are members of the same phoneme in Russian.

*Phonetic Transcription.*—It is, of course, impossible to assign a symbol to every known speech-sound. An unambiguous representation of a given language is effected when a distinctive symbol is assigned to each phoneme, for it is only by the phonemes of a language that words are distinguished in meaning. A "broad" system of transcription is now defined as one which provides one letter per phoneme; such a type of transcription is adequate for most practical purposes. A more elaborate system ("narrow") is often necessary in comparative phonetics and in recording dialects with minute accuracy. Narrow forms of transcription may also be useful, in helping to remember the rules governing the use of subsidiary members of phonemes.

*Intonation.*—The subject of intonation (the rise and fall of voice-pitch) has received much attention since 1910. Researches into the sentence intonation of English, French and German have resulted in the discovery that the apparently complex intonations of these languages are reducible to systems consisting of a few simple rules. Each language is found to have certain characteristic "tunes" which undergo modifications under special circumstances, such as the two kinds of emphasis ("prominence" and "intensity").<sup>3</sup>

<sup>1</sup> Letters in square brackets are phonetic symbols (International Phonetic System).

<sup>2</sup> Double-sided record No. B 804 in the catalogue of the Gramophone Co. (363 Oxford St., London, W. I.).

<sup>3</sup> The first comprehensive work on intonation was H. Klinghardt and M. de Fourmestaux's *Französische Intonations-übungen* (1911, rev. ed. 1925, Eng. ed. 1923); other notable contributors are H. Klinghardt and G. Klemm *Übungen im Englischen Tonfall* (1920); H. E. Palmer, *English Intonation* (1922); M. L. Barker, *Handbook of German Intonation* (1925); H. Klinghardt, *Deutsche Intonation* (1926).

Valuable research work has been done on the intonation of "tone languages" (Pekingese, Cantonese, Burmese, Japanese, Punjabi and various African languages). It has been established that in most "tone languages" the tones of words in connected speech are often different from the tones of the same words when said by themselves; the actual tones used may be grouped into "tonemes," just as phones are grouped into phonemes. It has been found that in Bantu and in Japanese tones are used not only to distinguish words of entirely different meaning but also to perform grammatical functions such as the distinction between different parts of the same verb. Details of some recent investigations will be found in several of the books given in footnotes to the next paragraph, also in Beach "Tonetics" in *Bantu Studies* (Dec. 1924).

*Languages Analysed since 1910.*—Languages of which a partial or fairly complete phonetic analysis has been made for the first time since 1910 include Pekingese,<sup>1</sup> Cantonese,<sup>2</sup> Burmese,<sup>2</sup> Panjabi,<sup>2</sup> Bengali,<sup>3</sup> Sinhalese,<sup>4</sup> Zulu,<sup>5</sup> Yoruba,<sup>6</sup> Yaunde,<sup>7</sup> and a number of other African languages.<sup>8</sup> Important additions have been made to our knowledge of the phonetic structure of several European languages (including Welsh,<sup>2</sup> Russian,<sup>9</sup> Polish<sup>2</sup>) and the non-European languages, Arabic,<sup>10</sup> Japanese,<sup>11</sup> Sechuana,<sup>2</sup> Hausa<sup>11</sup> and other African languages.

The study of these languages has brought to light many new phonetic facts besides tone systems, e.g., the true nature of affricates (such as the numerous sounds represented by *ch* by English writers on Eastern languages), the existence of "sulcal" sounds (sounds formed with a furrow down the middle of the tongue), voiced "implosive" (suctional) sounds (as in Sindhi), and *p*, *t*, *s*, and other sounds with simultaneous glottal stop.

*Increasing Use of Phonetic Methods in Practical Language Teaching.*—The use of phonetic methods, with or without the help of a phonetic transcription, is now recognised as essential by the foremost language teachers in many countries, especially in England, Germany, Scandinavia and Japan. These methods are now used in a great number of secondary schools in England, chiefly in connection with the teaching of French; they are also used in many training colleges for the purpose of enabling the students in training to become efficient teachers of English pronunciation. During the last 14 years several official reports have appeared in which phonetic methods are advocated: *Board of Education report on the teaching of modern languages, circular 707* (1912); *Report of a conference on speech training*, issued by the London County Council (1916); *London County Council report on the teaching of French in secondary schools* (1917); *Report of the Government Committee on the teaching of English in England* (1921); *Report of the Government committee on Modern Languages* (1918). The necessity for phonetic research in connection with Oriental and African languages was emphasised by the *report of the Government Committee* (1918), and phonetics has now for some years been included as a subject for candidates for the Indian Civil Service.

*BIBLIOGRAPHY.*—Among recent books dealing with methods of language teaching, in which the use of phonetics is advocated, may be mentioned W. Ripman, *The Early Teaching of French* (1915); H. E. Palmer, *The Scientific Study and Teaching of Languages* (1917); H. G. Atkins and H. L. Hutton, *The Teaching of Modern Foreign Languages* (1920).

**PHONOGRAPH** (see 21.467).—The progress which has been made since 1910 in phonographic reproduction of sounds has resulted in two chief improvements. First, notes of speech or music, which formerly presented great differences in their degrees of reproducibility, may now be reproduced with such evenness and impartiality that the ear can scarcely detect any difference between the effectiveness of reproduction of one note and that of another. Secondly, the range of notes which may be effectively reproduced has been extended from about  $3\frac{1}{2}$  octaves to approximately  $5\frac{1}{2}$ , nearly  $1\frac{1}{2}$  octaves being added at the lower end of the scale and about  $\frac{1}{2}$  octave at the higher end.

*Effects of Electrical Recording.*—These improvements were effected chiefly through the substitution, for the former mechanical linkage, of an electrical linkage between the diaphragm receiving the initial sound waves and the stylus recording their equivalents on the wax record. This electrical linkage consists of a vacuum tube amplifier and associated circuits, its purpose being to increase the power delivered by the transmitter whose diaphragm receives the initial sound. This increased power is used for operating the recording stylus. It is, therefore, no longer necessary to design the receiving diaphragm and the mechanism for driving the recording stylus with a view to their sensitivity; instead, the objective is to ensure that they follow, with maximum faithfulness, the vibrations of the initial sound waves. The above applies to the making of records in large auditoriums, as well as in the studio.

*Reproduction.*—Progress has likewise been made in the reproducing of the sound from the records. The vacuum tube amplifier (see **AMPLIFIERS**) may be used also in the linkage between the device operated by the needle following the grooves of the record and the diaphragm creating the sound waves for the listeners' ears. The sound may thus, if desirable, be greatly magnified. In the home, however, where this magnification is not necessary, a mechanical reproducing system in which great improvements have also been effected, is sufficient and simpler.

*Material.*—Another major improvement concerns the material and manufacture of the finished record, whereby the surface noise or "roar" has been materially reduced. In some cases this has been effected by laminating the record, the body consisting of a cheap, hard material to which adheres paper coated with the high-grade grooved material.

*Result of New Methods.*—By reason of the improved methods of making the records, the artists are now free to perform in a more natural manner than formerly, and at such a distance from the "pick-up" device that the normal reverberations from the studio walls may be duplicated in the recorded sound.

Figs. 1 and 2 on plate show, respectively, a group of artists recording by the old method and the same group recording by means of the electric process. It will be noticed in fig. 1 that the artists were grouped very closely about the horn. Only two of the violins were of standard construction, the rest being of the type known as the "Stroh," strung in the manner of a violin but so arranged that the bridge vibrates a diaphragm attached to a horn. This horn was directed toward the recording horn, as shown by the player in the foreground. With such an arrangement of musicians, it was very difficult to arouse the spontaneous enthusiasm which is necessary for the production of really artistic music.

In fig. 2 the musicians are sitting at ease more nearly in their usual arrangement, and all are using the instruments which they would use were they playing at a concert. Furthermore, the pick-up device is now sufficiently far away from the orchestra to receive the sound in much the manner that the ears of a listener in the audience would receive it. In other words, it picks up the sound after it has been properly blended with the reflections from the walls of the room. It is in this way that the so-called "atmosphere" or "room-tone" is obtained.

*Effective Limits.*—The range of effective sound reproduction has now been increased virtually to the limits inherent in the material from which records are made. The limit at the lower end is fixed by the fact that a very low frequency note will cause the recording needle to cut from one groove into an adjacent one

(or, in a vertical cut, will penetrate so deeply as to tear the wax instead of cutting away with a clean surface), while, at the upper end, it is fixed by the cuts in the record becoming so fine and sharp that the reproducing needle will not follow them. The increase in effective range of notes recordable by the new process has resulted in the virtual elimination of metallic tones, characteristic of the earlier phonographs, and of the muffled quality of higher notes, provided the reproducing machine covers a similar range. The sibilants, also, which failed formerly to make themselves heard, may now be reproduced naturally.

The latter two improvements are due to the accurate recording and reproducing of the higher harmonics, vibration frequencies

cycles per sec. ( $1\frac{1}{2}$  octaves above the lowest note on the pianoforte), the result has gained remarkably in naturalness.

**Recording Methods.**—Fig. 1, a diagrammatic sketch of one of the recording instruments and of the equivalent electric circuit, shows the manner in which the recording needle is controlled in response to the voltage fluctuations set up by the sound-receiving diaphragm. This instrument is a mechanical filter of the low pass type, providing the two undesignated condensers are omitted. In this particular case the filter has three sections and a terminating resistance. In designing mechanical analogues of such a system, the problem presented is threefold: first, that of arranging the parts so that they form repeated filter sections; second, determining the magnitudes of these parts so that the separate sections all have the same characteristics; third, providing the proper resistance termination. The necessity of meeting these three conditions simultaneously probably prevented the solution of this problem by cut-and-try (non-scientific) methods. The credit for the use and design of such mechanical analogues for this purpose is due in large part to H. C. Harrison.

Such a filter when properly designed will secure a sensitiveness at the various pitches represented by curve A in fig. 2. The actual recorder, however, owing to the presence of the two undesignated condensers shown in fig. 1, has a loss of response at the low pitch end as indicated by curve B (fig. 2). This loss is unfortunately necessary in order to avoid the large amplitudes which accompany the low pitched notes and which would cause the trace on the record to cut from one groove over into its neighbour.

**Systems Employed.**—Many early attempts were made to design mechanical transmission systems having a wide frequency range in which highly damped single or multi-resonant systems were employed. In these attempts both of the obvious methods of increasing the damping were used, namely, that of adding a resistance to the system and that of increasing the value of the compliance and decreasing mass in such proportion as to maintain the same natural frequency. The results of these two methods are shown in fig. 3. The former reduces the sensitivity of the system at the point where it is most efficient (curve B as compared with curve A, which represents the response of the singly resonant system chosen for illustration). The second method increases the response at the points where the system is less sensitive, namely, away from its resonance point (curve C, as compared with curve A). Curve D represents the response when a band pass type of system is used whose resistance impedance is the same as that of the system shown in curve A.

Some of the earlier attempts to improve the range of reproduction employed multi-resonant systems. The results of the filter theory have shown how these resonances should be coordinated so that, when a proper resistance termination is used, high efficiency and equal sensitivity are obtained over a definite band of frequencies by elimination of response to all frequencies outside the band. With either the electrical or the mechanical

FIG. 1.—The inductance labelled  $m_1$  represents the mass of the armature which, when acted on by the magnetic field, forms the driving portion of the mechanical system. The condenser  $c_1$  produces the flexibility of the shaft connecting the armature to the stylus holder;  $m_2$  represents the mass of the stylus holder and stylus;  $c_2$  the flexibility of the shaft connecting the stylus holder with the metal piece which fits into the rubber damping element;  $m_3$  the mass of this metal piece; and  $c_3$  and  $R$  represent the properties of the damping element. The two condensers shown dotted and unlabelled represent the effect of the magnetic field on the armature and the restoring force of the balancing springs which hold the armature in its central position.

up to 6,000 cycles per sec. being successfully recorded, i.e., about  $\frac{1}{2}$  octave above the highest note on the pianoforte. The elimination of metallic sounds is due to accuracy in recording and reproducing low notes and to the impartiality with which the various notes are treated. In the earlier machines, the fundamentals of the lower notes failed to be reproduced, but the ear of the listener, hearing the higher frequency harmonics of these notes, added the fundamentals, although the result lacked "body" and sounded "tinny." Were it not for this constructive faculty of the ear, the older phonographs and loud-speakers would have been useless. With the recently attained accuracy in actually reproducing the fundamentals of tones as low as 100

FIG. 2.—Curve A shows the response, that is, current, in the series branches of a low-pass filter as a function of pitch. Curve B shows a calibration of one of the recording instruments.

FIG. 1. Scene in recording studio, showing the means required with the older phonograph to create the necessary power for marking the record. The artists are grouped closely about the horn, and the weaker instruments (violins) are specially equipped with amplifying horns. FIG. 2. Studio scene, for recording by means of newer devices. The artists, playing naturally, are at a distance from the receiver, which picks up the sound after it has been properly blended with reverberations from the walls of the room.

case of a repeating filter, each section considered by itself resonates at the same frequency, but when combined into a short-circuited filter of  $n$  sections there will be  $n$  natural frequencies. However, when such a system is terminated with a resistance

FIG. 3.—Diagram showing response for various values of mechanical constants.

which equals the nominal characteristic impedance in the transmission band, uniform response in the terminating resistance is obtained over the entire band.

**New Phonograph.**—Fig. 4 shows a diagrammatic sketch of the mechanical system of the new phonograph, while fig. 5 shows the equivalent electrical circuit. From these diagrams it is evident which units in the mechanical system correspond to the various electrical parts. As the series flexibilities  $c_2, c_4$  and  $c_6$  have been made so large that the low frequency cut-off caused by them lies well below the low frequency cut-off of the horn, an inappre-

FIG. 4.—Diagrammatic sketch of the mechanical recording system of the phonograph.

ceptible error is introduced in using for design purposes formulae of low-pass filters.

The two formulae which have been used are as follows:—

$$f_c = \frac{1}{\pi} \sqrt{\frac{1}{mc}} \quad (1) \quad z_0 = \sqrt{\frac{m}{c}} \quad (2) \quad \text{where } f_c = \text{cut-off frequency}$$

frequency of a lumped transmission system in cycles per second,  $c$ =shunt compliance per section in centimetres per dynes,  $m$ =series mass per section in grammes,  $z_0$ = value of characteristic impedance over the greater part of the band range. This may be called nominal mid-shunt or mid-series impedance. Their actual values in the transmission band being at any frequency  $f$ , mid-series  $= z_0 \sqrt{1 - \left(\frac{f}{f_c}\right)^2}$  mid-

$$\text{shunt} = \frac{z_0}{\sqrt{1 - \left(\frac{f}{f_c}\right)^2}}$$

Equations (1) and (2), which form the basis of the design work, contain four variables,  $f_c, c, m$  and  $z_0$ . It is, therefore, necessary to determine two of them by the physical requirements of the problem,

after which the other two can be determined mathematically. The upper cut-off frequency  $f_c$  was arbitrarily chosen at 5,000 cp. as a compromise between the higher frequencies occurring on the record and the increase in surface noise as the cut-off is raised. The choice of the other arbitrarily set variable came after considerable preliminary experimenting, and was fixed by the difficulty of obtaining a diaphragm which is light enough and has a large enough area. Hence the effective mass of the diaphragm  $m_3$  (figs. 4 and 5) was fixed at 0.186 grammes, which value can be obtained by careful design. The effective area can be made as large as 13 sq. centimetres.

**Design of the Horn.**—By the proper use of these two formulae with the two arbitrarily set variables it has been possible to determine mathematically the magnitude of the parts comprising the mechanical system. When this design is complete there still

FIG. 5.—Electric equivalent of the system shown in fig. 4.

remains the terminating resistance,  $z_h$ , of figs. 4 and 5. This is supplied by the horn, which has been made of the logarithmic type. Certain general properties of logarithmic horns have been understood for some time.

There are two fundamental constants of such a horn—the first is the area of the large end and the second is the rate of taper. The area of the mouth determines the lowest frequency which is radiated satisfactorily. The energy of the frequencies below this is largely reflected if it is permitted to reach the mouth. From the equations given by Webster,<sup>1</sup> it can be shown that all logarithmic horns have a low frequency cut-off which is determined by the rate of taper. If the rate of taper is so proportioned that its resulting cut-off prevents the lower frequencies from reaching the horn mouth, the horn will then radiate all frequencies reaching its mouth and very little reflection will result. It is, therefore, possible to build a horn having no

<sup>1</sup> Much credit is due to P. B. Flanders, who carried out the mathematical investigation of these relationships; and to A. L. Thuras, who developed a method of checking experimentally the mathematical theory.

marked fundamental resonance. Since the characteristics of the horn are determined by the area of its mouth and by its rate of taper, the length of the horn is determined by the area of the small

FIG. 6.—Sectional view of folded horn.

end. This area is determined in turn by the mechanical impedance and effective area of the system which it is terminating. It is seen, therefore, that the length of the horn should not be considered as a fundamental constant.

An interesting feature of the horn which has been built commercially is its method of folding. The sketch in fig. 6 shows a shadow picture of the horn. It will be noticed that the sound passage is folded only in its thin direction, which permits the radius of the turns to be small and thereby makes the folding compact. Fig. 7 shows the sensitiveness at various pitches of a phonograph designed as described above with a logarithmic horn whose rate of taper and area of mouth opening place the low cut-off at about 115 cycles. It also shows a similar curve for one of the best of the old style phonographs. Curve A represents the new machine, while curve B represents the old style machine. With this new equipment, it is easily possible for a listener to receive the full artistic effect of the music which is being reproduced, and with certain types of music it is no exaggeration to say that he may have the feeling of actually being in the presence of the artist. (See SOUND.)

**PHOTOELECTRICITY.**—Hertz noticed in 1887 that an electric discharge passed more easily between two neighbouring conductors when the negative electrode was illuminated by an electric spark. Hallwachs and others demonstrated that an insulated metallic conductor loses negative electricity when illuminated by light of short wave-length. This loss, observable in vacuo as well as in gases, is known as the photoelectric effect. It is proportional to the intensity of the illumination and to the time for which it acts. It varies with the wave-length of the light, and for each metal there is a wave-length for which the effect is produced. For the alkaline metals this critical wave-length is in the visible part of the spectrum.

Towards the close of the 19th century Sir Joseph Thomson and Lenard showed by exact experiments that negative charges were formed by the emission of electrons, and that the photoelectrons thus projected possessed a relatively small velocity (of the order of  $10^7$  cm. per second). Curie and Sagnac proved a similar phenomenon in the case of Röntgen rays.

C. T. R. Wilson showed later that ionisation in gases through which X-rays pass is really due to the formation of ions within the gaseous medium, by the rapid photo-electrons removed from the molecules under the influence of radiation.

All electronic emissions can be measured as to: (a) the number of corpuscles emitted per unit of time, and (b) their individual velocities. Investigations to determine these values in the case of photoelectrons showed that although the intensity of the exciting radiation affects the number of electrons emitted, their maximum velocity is entirely unaffected (Lenard), this latter quantity, or rather the energy of each corpuscle (Richardson, Hughes, Compton), depending solely upon the wave-length of the rays employed, and being a linear function of the frequency of the exciting radiation. This law, the extent and scope of which has been pointed out since 1905 especially by Einstein, is bound up with the quantum theory of light (see QUANTUM THEORY).

Denoting the frequency of the exciting rays by  $\nu$  and Planck's constant by  $h$ , the following relation for the energy of the electrons holds:—

$$\frac{1}{2} m v^2 = V e = h \nu - k. \quad (1)$$

Where the velocity of the photoelectrons is sufficiently great to cause a variation of their mass with kinetic energy to be appreciable the above relation must be written in the form:—

$$h \nu = m_0 c^2 \left( \frac{1}{\sqrt{1 - \beta^2}} - 1 \right)$$

From the numerical point of view it is convenient to express the electronic energy ( $\frac{1}{2} m v^2$  when the velocities are insufficient to cause the variation of the mass to intervene) in the form  $eV$ , where  $e$  is the electronic charge and  $V$  the difference of potential required to impart the energy to the electron. The electronic charge being constant, it follows that each electronic velocity is characterised by a definite voltage, and we may write the quantum relation (1) in the form:—

$$V = \frac{12 \cdot 345}{\lambda}$$

where  $V$  is expressed in volts and the wave-length  $\lambda$  in Ångström units.

Consideration of the relation (1) shows that the slope of the straight line representing the relation between the energies of the frequencies, is exactly equal to Planck's constant  $h$ , and moreover the phenomenon must present a threshold when the frequency of the exciting radiation is just sufficient to overcome the work of extraction  $K$ .

The minimum frequency of the light required to produce a photoelectric effect proceeds continuously towards the red end of the spectrum as the illuminated body becomes more electropositive (alkaline metals): it was thus hoped to obtain for each body a critical frequency which would have been of significance. Unfortunately, parasitic effects due to contact differences of potential have prevented the exact determination of these constants.

Research has given to photoelectric phenomena a significance of increasing importance, since the loss of electrons which may be produced either by corpuscular shocks or by the emergence of radiation is, in reality, the preliminary excitation which conditions the emission of spectral rays by the atoms. (SEE ATOM; ATOMIC ENERGY.)

In the Rutherford-Bohr atomic model the electrons are imagined as rotating around a nucleus and divided into layers or levels characterised by their energy or emission. When a radiation of high frequency, such as X-rays, strikes an atom, it may communicate to an electron of the K layer, for example, energy equal to its quantum—that is to say, remove a photoelectron which possesses, on coming out of the atom, kinetic energy equal to the quantum of the incident radiation, diminished by the energy of emission. At the same time, the re-arrangement of the electrons which restores the atom to the normal state will be accompanied by the emission of the spectral series corresponding to the electronic layer involved.

In the case of rays of lower frequency (ultra-violet, visible light) the energy absorbed may carry the electron to a level further removed from the nucleus, without extracting it completely (resonance potential); when the quantum absorbed is sufficiently large the electron is expelled as in the case of X-rays (ionisation potential).

The study of photoelectric phenomena is simplified when the velocity of the electrons emitted is sufficiently great for them to travel an appreciable distance, thus rendering negligible the contact potential differences experienced in the case of solids and liquids. The action of high frequency rays like X-rays is therefore better known than that of the ultra-violet and visible rays, which can act only upon the superficial electrons of the atom, that is to say those feebly bound electrons which play such an important rôle in the phenomena of conduction, cohesion and chemical affinity. At the present day explanations of photoelectric phenomena start from the absorption of light by a Rutherford-Bohr atom obeying Einstein's law, and the phenomena first studied, the charge of illuminated conductors follow in consequence of this principle.

The emission of electrons produced by ultra-violet and visible light has been the object of much experimental and theoretical work. O. W. Richardson has considered the relation between photoelectric and thermionic effects particularly from the theoretical point of view. Millikan has studied the influence of the contact potential differences on the emission of electrons when different metals are illuminated in vacuo by ultra-violet rays.

Ever since the researches of Elster and Geitel, physicists (in the case of radiations of low frequency) have distinguished between a normal and a selective effect. In the case of the selective effect the intensity of the effects observed depends upon the orientation of the plane of polarisation of the incident light, so that if the liquid, sodium-potassium alloy for example, is illuminated, the maximum result is obtained when the electric vector vibrates in the plane of incidence.

The photoelectric effect is exactly proportional to the intensity of the light received, and this property is utilised in photometry by means of photoelectric cells—the current of which may be amplified at will. They furnish at the present day the most sensitive and precise instruments for measuring very feeble radiation intensities. Astronomical physics, in particular, makes great use of them.

Radiation may produce the ejection of electrons in matter under bombardment by a very different process; A. H. Compton has shown that the diffusion of X-rays may be accompanied by an increase of the wave-length (that is to say, a diminution of the quantum associated with the radiation) and at the same time by the emission of a "recoil electron" whose kinetic energy is exactly equal to the loss of quantum suffered by the incident radiation.

By this theory the encounter between an electron and a quantum of light is compared with a ballistic collision in which the energy and momentum are conserved.

**PHOTO-ENGRAVING** (see 22.408).—This term is applied properly only to those photomechanical processes of reproducing pictures which print from a relief plate. This article, however, deals with similar processes which print from flat surface (planographic) and from sunken lines (intaglio). In Great Britain the term "process" is generally employed instead of "photo-engraving."

**Essential Principles.**—By sensitising a metal plate and by photographically printing an acid-resist on it, which protects certain areas, and then etching the unprotected parts with acid, a relief, or intaglio, plate is produced, which can be inked and mechanically printed. All photomechanical reproductive processes are based on the fact that pictures are made up of small grains or dots, whether they be of ink, of paint or of photographic emulsion. Concentration of these small grains or dots, bringing them closer together, gives, when printed, a solid colour, while distribution or scattering so that the grains are farther apart, gives a tone—a colour not solid, but tending in some degree toward white. Therefore, to reproduce solids or tone, it is only necessary to reconstruct a grain or dot formation on a printing plate or on a printing medium, which will transfer printing ink to paper in the same ratio of concentration as that which produced the tones of the original. Grain or dot formations differ in the numerous processes. Some are irregular as produced by gelatine colloids, resin or bitumen dust, while others are symmetrical, resulting from the ruled cross line half-tone screens.

**Relief or Cameo.**—Relief plates have their printing elements on a plane; the areas between them are sunken. Ink is applied to the surfaces by means of a roller and printing is effected by transfer of the ink from the relief areas to the paper. The printing elements vary in size, but all print with a uniform intensity.

**Plano or Flat.**—Planographic printing is done from metal, stone, gelatine or other suitable material, on which the image has been formed of a greasy ink. The surrounding areas, comprising the spaces between the grains or dots, have an affinity for moisture and when so impregnated reject greasy ink.

In printing, both water and ink rollers are used. The former keeps the un-inked surfaces damp, so the deposit from the ink roller will adhere only to the image to be printed. The materials used for some classes of planography are impregnated with ink repellents, such as mercury. These require no water roller, the repellent acting in its stead. As with relief plates the printing elements in planography print with uniform intensity, but they vary in size.

**Intaglio or Sunken.**—Intaglio plates have their lines, dots or grains sunken like grooves or cups. The printing ink is forced into the depressions and scraped or wiped off the surrounding higher areas. Printing is done with considerable pressure, usually on dampened paper, which sinks into the depressions and extracts ink from them. The depth of the grooves or cups is proportionate to the intensity of tone. The deposit of ink extracted from them varies therefore in thickness and, as it is transparent, yields a range of tone proportionate to its density. Unlike the other two groups, intaglio plates depend not upon the variation in size of the pointing elements but upon their different intensities.

**Action of Light.**—There are some 10 different photomechanical processes included in the three general groups, and many more

subdivisions of each, but all have for their basis the phenomenon of the action of light, through a negative or diapositive, on a bichromated emulsion. Gelatine, glue, shellac, bitumen and other similar materials, in solution with ammonium bichromate or potassium bichromate, when spread on a supporting base and dried, are rendered insoluble in a ratio directly proportionate to the intensity of light to which they may be exposed. Relief and intaglio plates, which are etched, employ this principle to obtain an insoluble photographic image which will act as an acid-resist. All areas not so protected will be subject to attack by the etching acid. In planography, the insoluble areas retain ink and reject moisture, while the soluble hold moisture and reject ink. These principles are fixed, but their application varies in the different processes.

**Photo-Engraving.**—Photo-engraving comprises two classes of plates, line and half-tone, although there are many combinations and modifications of these two. A line plate is made from an original comprising definite lines, grains or dots of sufficient size to permit their being photographed, printed on metal and the areas between them etched. If the original comprises tones, as in a photograph or painting, then a half-tone must be employed to reproduce it. It is photographed through a ruled glass cross line screen, placed slightly forward of the photographic plate in the camera. The light from the original, forming the image, spreads in passing across this intervening space, producing dots which vary in size proportionately to its tones.

The metal, usually zinc or copper, is coated with a bichromated emulsion and the line or half-tone negative placed in contact with it and exposed to light. That which passes through the transparent areas of the negative renders the emulsion insoluble. The print is washed, removing all soluble emulsion, and heated, producing an insoluble acid-resist of all lines or dots as photographed. The areas between these are etched, leaving the printing elements in relief. Early relief processes included the swelled gelatine and the washed-out gelatine methods. In the former the gelatine was bichromated and printed from a negative. The soluble areas were then saturated with moisture and allowed to swell sufficiently to make an intaglio of the image, which was then moulded and electrotyped. The washed-out method required that the emulsion be printed in a similar manner, but the gelatine was thicker and the soluble areas were washed away to give the necessary relief for printing.

**Photo-Lithography.**—This art in its various branches, comprises the entire photomechanical planographic group. Only when the lithographic stone is used as a base, is it lithography. When on metal it is called planography, and when on gelatine it is called collotype. The latter embraces such methods as Albertype, Artotype, Heliotype, Gelatine Printing, Aquatone and Sperati. The Sperati Process has the ink repellent incorporated in the base and requires no dampening roller.

The general procedure in all planographic methods is to use a bichromated albumen or gelatine emulsion, printed from either a line, half-tone or continuous tone negative, only the insoluble areas retaining the greasy ink. The sensitised emulsion may be spread on the stone or metal before being printed, or may be printed on one base and transferred to another by means of transfer paper. In the Albertype, Artotype and other similar methods, the colloids of gelatine are employed to produce the tone variations, each colloid acting as an individual grain or dot. A development in the printing methods of planography is to print from the metal plate to a cylinder covered with a sheet of rubber called an offset blanket. This in turn prints on the paper the pliable blanket conforming under pressure to the inequalities of the paper. Aquatone employs certain features of three different methods. The base is a patented substance, bichromated, and printed from a line or half-tone negative. The printing is by offset.

**The Intaglio Group.**—This group includes photogravure, rotogravure, with its many trade names such as rotogravure, alcogravure, art gravure and others, as well as photo-intaglio line engraving and photo-intaglio half-tone engraving. In each of the gravure methods a continuous tone (screenless) diapositive

is used instead of a negative for photographic printing. As the tonal ranges result from a variation in the depth of each dot or line rather than from their size, it is not necessary to use a half-tone negative. It is essential, however, to establish a cellular structure of grains or dots which may be etched in varying depth.

*Rotogravure.*—In this a special screen of transparent lines is first printed on a bichromated gelatine base mounted on a paper backing. The diapositive is then surprinted and the print developed by washing. The finished print is transferred to a copper cylinder and the paper backing stripped off. The image is represented by gelatine in varying thickness representing its tone range. While insoluble, the gelatine is porous, and in the etching the acid solution seeps through to attack the metal. The seepage is proportionate to the thickness of the gelatine, and a variation in etched depth results. The printing ink is quite fluid and is cleanly scraped off the surface by a thin, razor-edged blade, called a "doctor."

*Photogravure.*—In this the plate is flat, and a fine bitumen or resin dust is dropped on it until the metal is about half obscured, which is to say that the area of grains is about equal to the areas of exposed metal. The plate is heated, melting the grains and forming a resist called a "ground." The print is made on sensitised gelatine, developed and transferred to the prepared metal. The etching principle is similar to that employed in Rotogravure, but the spaces between the grains resolve into irregularly shaped cups which vary in depth. A somewhat stiff ink is forced into the depressions and wiped off the surface.

*Photo-intaglio.*—Photo-intaglio line engravings are etched after producing on the metal a resist made by printing from a line diapositive. Photo-intaglio half-tone engravings are similar in principle, but are printed from a half-tone diapositive. These methods differ from the rotogravure and photogravure in that the lines or dots, while etched into the metal, print with a variation in size but not in intensity. In different localities these various processes and methods are known by different names, hence it is impossible to classify them under a universal title, but they have all been described here under photo-engraving, and the subdivisions separately indexed under the descriptive titles generally employed. (See also PRINTING.) (H. A. GK.)

**PHOTOGRAPHY** (see 21.485).—In this article photography is treated under four different heads. The first is introductory and general covering, among other topics, amateur, professional and aerial photography, radiography and amateur cinematography. The second deals with photographic manufacture; the third, with colour photography; and the fourth is an account of the general principles of photography in the light of recent knowledge.

## I. INTRODUCTORY AND GENERAL

Photography is now applied to very many fields. It is employed in astronomy—in which photographic has almost superseded visual observation—microscopy, spectroscopy and many other fields of science, for a discussion of which reference must be made to the corresponding articles.

*Amateur Photography.*—The use of photography for making personal records has extended very greatly since portable cameras and sensitive materials were introduced, and the tendency is continually towards a simplification of the work to be done by the user and a diminution in the amount of expert knowledge required to get good results. This has resulted in the establishment of commercial firms to develop and print photographs made by the amateur, so that the great majority of photographs are now taken by those whose knowledge of the subject is limited to that necessary for making the exposures. The cameras used are chiefly of the folding type using a cartridge of film and often of very small size.

The film can be loaded into the camera without the use of a dark room and removed after exposure for development. After an exposure has been made, an inscription may be written with a stylus on the red paper protecting the *autographic* film. The

pressure of the stylus removes the dark-coloured wax from the "carbon" paper. An opening in the back of the camera where the writing is done is then exposed to light, which penetrates the translucent red paper and prints the inscription on the film. For development, the films are hung by clips in deep tanks and are then printed by artificial light upon gaslight or developing-out papers which are made in different degrees of contrast to suit the negatives obtained. As a general rule the photographic dealers will deliver prints from an exposed roll of film within two days. Enlargements are made upon bromide paper, frequently by means of enlarging cameras in which the focus is automatically maintained correct while the scale of magnification is varied (see fig. 1 on plate). In addition to roll films, films in packs are largely used, each separate unit having a tab of paper attached to it by which it can be withdrawn after exposure. A small number of cameras still use plates or flat cut out films in suitable holders.

Almost all the cameras used in amateur photography are designed primarily for use in the hand and are only occasionally used upon tripods. In addition to the small portable cameras, many amateur photographers use reflex cameras and folding cameras fitted with focal plane shutters. A number of makers have introduced lenses working at very large apertures  $f/2$  and  $f/2.5$  (see fig. 4 on plate) and special cameras fitted with these lenses have been used for photography in ordinary rooms and under poor light conditions (see OPTICAL GLASS). Such equipment is very valuable under extreme conditions, but has the limitation that large aperture lenses have little depth of focus and consequently must be focused very exactly if good results are to be obtained.

*Professional Photography.*—This may be divided into the two great fields of portraiture and commercial photography. Portrait photographers are tending more and more to work by artificial light, thus rendering themselves independent of the variations of daylight. Large units employing mercury vapour lamps, arc lamps and nitrogen tungsten incandescent lamps are now available. The materials used by the portrait photographer are plates or flat films. There is a growing tendency to make negatives not larger than 5 in.  $\times$  7 in. and to make the prints by projection. As a printing material, the gelatino-chloride printing-out paper has been supplanted almost entirely by developing-out papers. In England, bromide paper is very generally used, while in the United States a slower chloride paper is employed professionally, some grades of this paper having a long scale suitable for printing from the high quality, professional negatives. Portrait prints are no longer intended for insertion in albums and are supplied generally in card folders. Lightings are of the most varied type, and of recent years many unusual lightings have been introduced as a result of the influence of the motion picture upon the work of the professional photographer.

Commercial photography is now very wide in its field, a large number of advertisements being illustrated photographically and photographs often taking the place of samples in the hands of salesmen. Commercial photographs are printed usually upon glossy papers and are mounted upon linen in such a way that they can be handled and filed conveniently. They are not infrequently tinted by hand, a practice which has almost gone out of use for other fields of photography.

*Aerial Photography.*—Photography from the air is utilized for military purposes as well as for surveying. Its use during the World War was very extensive, thousands of negatives being taken every day by the armies. The first aeroplane cameras were modifications of standard cameras with usually a focal plane shutter, and the material was generally plates carried in holders and later in magazines adapted for quick changing. Hand-operated cameras using magazines were later developed and were used largely in 1916 and 1919. Later, semi-automatic plate cameras were designed in which the observer released the shutter while the mechanism operated the changing of the plates. In the last years of the War these cameras were made of very considerable size and weight, sometimes as many as 50 plates 18 cm.  $\times$  24 cm. in size being carried on a camera at one time. Towards the end

of the War film cameras were developed carrying rolls of film giving 100 exposures 18 x 24 centimetres. The great advantage of such cameras is, of course, the light weight of the material used. In 1918 entirely automatic film cameras were made, the changing of the film and the exposure being carried out by means of a motor, either electrical or driven by the wind (*see fig. 3 on plate*). In 1926 the automatic film cameras were used almost exclusively in the United States while plate cameras—either automatic or hand-operated—were still employed by the European air services.

From the photographic point of view the most important phenomenon encountered when working from a great height, as in an aeroplane, is the scattering of the light by the atmosphere, an effect which is generally known as *haze*. Since this scattering is greater for shorter wave-lengths of light, it can be eliminated to a considerable extent by the removal of the blue light and by the use of only longer wave-lengths. In order to accomplish this, the materials used are generally sensitive to red light, and filters can be used with satisfactory results as to exposure; under such conditions great penetration through hazy atmosphere is possible. Excellent photographs have been taken from the greatest height which an aeroplane can attain.

While aerial photography is an immense aid to the military both for the detection of enemy operations and also for the preparation of maps, its application to precision surveying is subject to limitations. It is not possible to note with sufficient accuracy the height and angle of the aerial camera for a map to be made without correction for errors, and consequently aerial surveying requires the provision of bases of known position on the ground which can be included and used to scale and correct the photograph. This limits its use in surveying (*q.v.*) since such measured bases are not always available. Nevertheless there are many purposes for which aerial surveying is very well adapted. A fire survey of a city can be made with sufficient accuracy by aerial photography at less than one-tenth of the cost of a corresponding ground survey. This makes it possible to repeat the fire surveys of rapidly growing cities at much more frequent intervals than could be done otherwise. Surveys of lakes and forests can be carried out by the aeroplane rapidly and with sufficient accuracy for many purposes. (*See ARCHAEOLOGY: Air Survey; SURVEYING.*)

**Radiography** (*see* RADIOTHERAPY; RÖNTGEN RAYS).—In this branch of photography very special conditions of work are involved. From its introduction in 1896, when X-rays were discovered by Röntgen, the field of radiography—almost entirely in connection with its medical application—has grown until at the present time approximately as many negatives are taken by means of X-rays as are made in portrait studies.

The earlier radiographs were made on plates of the same type as those used for portraiture; improvements were made by the introduction of large quantities of silver salt into the emulsion, while later attempts were made to load the emulsion by the addition of salts of other metals in such a way that the absorption of the X-rays would be increased and high sensitiveness obtained. There is reason to believe that these attempts were based on an incorrect understanding of the laws of the absorption of the X-rays. A considerable advance in the technique was made when double-coated film was introduced, a special X-ray emulsion being coated on both sides of the film, so that the image was formed half on the front and half on the back. In 1926 it was customary to use such films in combination with one or more, generally two, so-called intensifying screens. These intensifying screens consist of a layer containing calcium tungstate coated on a suitable support. The calcium tungstate fluoresces under the influence of the X-rays, transforming a portion of the X-rays into light which is active photographically. The general method of working, therefore, was in 1926 to expose the film in a cassette; that is, a holder in which the film is pressed into contact with an intensifying screen on each side.

One of the great difficulties in obtaining radiographs of good quality, especially when photographing through portions of the body of considerable thickness, is the presence of scattered radiation or secondary X-rays produced by the scattering of the

primary X-rays in the tissues. Measurements have shown that the scattered radiation generally accounts for as much as three-fourths of the entire density of a radiograph taken through the body, and since this scattered radiation does not contribute to the formation of the image, it naturally produces a great lowering of contrast and general loss of detail and quality. The only method found to eliminate this is the use of what is known as the *Potter Bucky* diaphragm in which a number of strips of lead are adjusted so that they point toward the source of the X-rays. In order to prevent their forming shadows, the diaphragm is moved during exposure, and under these conditions the strips of lead cut out much of the scattered radiation, which is not proceeding from the source of X-rays but is scattered in all directions, and thus enable the image to be formed to a much greater extent by the direct X-rays coming from the focal point (*see fig. 2 on plate*). For dental work the film is supplied in special packages to be held inside the mouth, usually with a backing of lead foil to stop secondary radiation and to enable the package to be moulded to the shape of the mouth. Dental radiography has been extending very rapidly, and in 1926 radiographs of the teeth were among the most valuable guides to the operations of the dental surgeon.

**Amateur Cinematography.**—Cameras have been placed on the market by means of which amateurs can take motion pictures without the use of the elaborate and expensive apparatus employed by the professional cinematographer. Some of these cameras, while of small size, use motion-picture film of standard width (35 mm.) and differ from professional apparatus only in the short length of the film which they take and in their low cost. Cheaper forms of projectors taking standard film are also supplied for the use of amateurs, but the cost of the films and their development and printing have prevented any rapid extension of the use of this apparatus among the general public. Cameras have been introduced taking sub-standard film particularly intended for use in amateur cinematography. Two sizes have been introduced: In France, a film 9½ mm. wide has been introduced by the Pathé Co.: 30 metres are supplied in magazines for use in a small camera (*see fig. 5 on plate*), and the film after exposure is developed by the user or by photographic dealers by means of a reversal process which transforms the original negative into a positive which is then ready for use in a projector.

The Eastman Kodak Co. in 1923 introduced a film 16 mm. wide to make a picture approximately one-sixth of the area of standard pictures, and they and other makers have placed on the market cameras and projectors adapted to take this small size of film (*see fig. 6 on plate*). The film is packed with paper leaders attached to the end in a special form of light-tight packing so that it can be placed in the camera without the use of a dark room, and after exposure the processing is done by means of a special reversal process which transforms the negative into a positive ready for projection and which it is claimed enables errors in exposure to be corrected to a certain extent during the processing, a sufficient degree of latitude in exposure thus being retained. Duplicates can be made from the original positives, standard size film can be reduced to the 16 mm. size and the 16 mm. film can be enlarged to give pictures of standard size, although in doing this a certain amount of graininess in the resulting print is inevitable. The reversal process gives to the original prints very great freedom from grain, so that when projected they are entirely satisfactory upon the screen.

The cameras supplied for this branch of photography are usually portable and are motor-driven so that once threaded, they require no attention until the film is finished. For all these amateur instruments copies of theatrical films from various libraries are available for use in the home, and it is probable that such small and portable projectors may also find an application in the school and lecture-hall.

## II. MANUFACTURE OF PHOTOGRAPHIC MATERIALS

The manufacture of photographic sensitive materials is a very specialised industry. Approximately 40,000 people are employed in the whole photographic industry throughout the world, about

FIG. 1. Autofocus enlarger; the size of the enlargement is varied by raising or lowering the lens, the focus being held automatically at the correct point. The negative is placed in the holder between the bellows and the lamphouse above it. FIG. 2. Radiographs made with (left) and without (right) the Bucky diaphragm. FIG. 3. 20,000 being engaged in the manufacture of materials sensitive to light, with which this section deals, and the remainder in the manufacture of cameras and in the wholesale distribution of the products to the retailer.

With the introduction of the gelatine dry plate, the preparation of materials by photographers for themselves diminished very rapidly, and the manufacture of ready-prepared material took its place. The first dry plates appear to have been placed upon the English market in 1877. In 1880 the manufacture of gelatine dry plates was general in England and was commencing in Belgium, Germany, France and the United States.

The prototype of the modern photographic film was made by coating upon paper emulsion of the kind used for making dry plates, the paper negative being printed, generally after preparation with oil or wax to make it more translucent. In 1885 paper in a roll intended for making negatives was introduced together with a roll holder fitting the back of the existing cameras, the paper being coated on a special coating machine from which was derived the present film and paper coating machines. Later, paper was coated with soluble gelatine so that the gelatine emulsion could be stripped from the paper base, and finally in 1889 emulsion coated upon a flexible film support made of nitrocellulose was placed on the market. This film was first made by spreading upon a glass table a solution of nitrocellulose which when dried was coated with a substratum to make the emulsion adhere and then coated with gelatine emulsion, the whole film being stripped from the table and cut up for use.

In 1891 a method of packing the film to make it daylight loading was devised, this being done by winding it inside a protective sheet of black paper of such a length that the camera could be loaded without exposing the sensitive film to light, and in 1903 the film used in cartridges was coated on the back with gelatine so as to counteract the tendency to curl produced by the coating of emulsion on one side.

In 1885 the coating of bromide emulsion paper by a continuous coating-machine was commenced, and about 1890 gelatine-chloride printing-out paper was introduced by Abney. In this paper the sensitive salts were a mixture of silver chloride and silver citrate containing an excess of free silver nitrate and also free citric acid. A similar paper prepared with collodion as the vehicle instead of gelatine was known in the United States as *Aristotype* paper and in Europe as *collodio-chloride* printing-out paper. With these printing-out papers a visible image was obtained by printing under a negative in bright light for a considerable time, and this image was then toned by the deposition of gold before fixation. In 1897 chloride emulsion papers were introduced; they were made without an excess of silver nitrate and therefore were suitable for development in the same way as bromide paper but differed from bromide paper in that the salts produced by the reaction of the silver nitrate with the soluble halide were not removed by washing. These papers are about 200 times slower than bromide paper and are known in the United States as *developing-out* paper and in England as *gaslight* papers.

Until 1900 the photographic industry was carried on in small factories under the direct personal control of the owner. At the present time, however, photographic manufacture is organised chiefly in modern factories manufacturing on a large scale, and using specially designed machinery at every step of the process. In the largest of these factories, the output of motion-picture film alone exceeds 150,000 m. in a year. Nearly 5,000,000 lb. of cotton are used each year for the manufacture of film, and over three tons of pure silver bullion are used each week. The total power required exceeds 20,000 H.P., and the consumption of coal is over 500 tons a day.

The process of manufacture may be divided into three distinct sections: 1. The preparation of the base; 2. The preparation of the emulsion; 3. The coating of the emulsion on the base and the cutting and packing of the material so prepared.

*Preparation of the Base.*—Photographic glass is the specially selected, best quality of thin sheet glass made in a factory which prepares sheet glass for all purposes. Even under the best con-

ditions only about a quarter of the sheets made are fit for photographic use, the remainder being used for glazing. Photographic glass is made very largely in Belgium in the factories near Charleroi, and in England at St. Helens. A considerable amount is also made in the United States. The glass is supplied cut to sizes which are multiples of those used by photographers. The glass arrives packed in straw in boxes holding usually about two gross sheets, and after unpacking and preliminary inspection, is cleaned by an automatic machine into which it is fed. The glass plate is received between rollers and passes through a strong solution of soda between revolving brushes which remove the dirt from the surface, and at the end of the machine is coated with a substratum, usually a weak solution of gelatine containing chrome alum, by means of which the emulsion is made to adhere to the glass. The glass is then dried in a heated oven, examined for defects, and if passed is packed in a tray and transferred to the coating-room.

In the manufacture of film base the first step is the preparation of cotton linters for nitrating, the treatment consisting of cleansing the linters very thoroughly and drying them. They are then nitrated in centrifugal machines and when they have absorbed the necessary amount of nitrogen—12–13%—the resulting nitro-cotton is soured in water and the washing commenced. This washing is a long process, and is continued until the material is entirely free from absorbed acid, after which it is dehydrated, the water being displaced by the alcohol. The dehydrated nitro-cotton is then dissolved in tumbling barrels or mixers in suitable solvents, those commonly employed being acetone and methyl alcohol, and at the same time the so-called softeners, such as camphor, are added, these resulting in a flexible film. The viscous nitro-cotton solution, which appears rather like honey, is known in the United States as *dope*. This is now spread out into a thin film by coating it on a travelling surface. In the United States the coating is generally done on to large wheels about four feet across and about 20 ft. in diameter which rotate slowly about their axes so that by the time one rotation is completed the solvents have been evaporated sufficiently to set the film, which can be stripped off the wheel, and dried further by passing through drums. The operation is thus continuous, the film base, as it is called, being prepared in rolls of about 2,000 feet. In Europe it is customary to coat a film about 24 in. wide upon a metallic belt from which the film can be stripped after one rotation in the same way as from a drum. The surfaces of these belts and drums must necessarily be prepared very carefully, the wheels being usually made with a highly polished nickel surface, while the makers of the belt machines recommend that they be coated with gelatine.

*Non-inflammable Film.*—Since cellulose nitrate is highly inflammable, supplying itself the greater part of the oxygen which it requires for combustion, there has been much work done on the preparation of film which is not inflammable. The most promising substance for this purpose is cellulose acetate prepared by treating hydrated cellulose with acetic acid and acetic anhydride in the presence of a suitable catalyst. Acetate film is slow burning, burning with about as much difficulty as thick paper, and should it catch fire it is very easy to extinguish. It has the disadvantage that on keeping it tends to dry out more rapidly than nitrate film and thus becomes brittle and while it is very suitable for use where proper precautions against fire cannot be taken, as where films are used in homes or schools, it has not the wearing qualities necessary for use in the motion-picture theatres, where the high speed of projection, the great heat of the projection lamps and the continued operation is a great strain upon the film.

During or after manufacture the film base is coated with a substratum to make the emulsion adhere and is then ready for coating. The thickness of the film base depends upon the use to which it is to be put. Base for use in the roll film cartridge is  $3\frac{1}{2}$  thousandths of an inch thick; motion-picture film,  $5\frac{1}{2}$  thousandths; and portrait and X-ray film used flat, about  $7\frac{1}{2}$  thousandths.

*Paper Base.*—Photographic paper base is generally made by mills which specialise in its manufacture, the chief factories for

this purpose being in Belgium, France and Germany; but in the United States the bulk of the photographic paper base is made in the same factory where the rest of the production of photographic paper is carried on. The paper is prepared very largely from rag stock, although a small amount of wood pulp is sometimes added. After inspection the raw rag stock is washed and digested and is then treated in the beater until its preparation is such that it will make a homogeneous, strong sheet. The making is done on Fourdrinier machines, and the sheet is given a tub sizing in addition to the sizing given in the beater. Great care is necessary to exclude traces of impurities and especially of metals such as copper and iron from the paper stock.

The paper is usually given a coating of baryta before it receives the photographic emulsion. In this process a suspension of baryta (barium sulphate) in gelatine is coated over the surface of the paper, several coatings being sometimes applied, and not infrequently the paper is calendered after baryta coating in order to get a perfectly smooth glossy surface. Baryta coated paper is transferred to the emulsion coating-room in rolls of about 2,000 feet.

**Emulsions**—Emulsions are of two general types: washed and unwashed. Emulsions to be coated on glass or film are always washed. In the first case the precipitation of the silver salts is effected by adding a solution (about 10% in strength) of silver nitrate to a small quantity of gelatine dissolved in a solution of the halide salts which, in the case of negative emulsions, are usually potassium bromide containing a small proportion of potassium iodide. When precipitation is complete, the emulsion is digested in order to produce an increase of sensitiveness, and the bulk of the gelatine is added so that when cooled it will set to a jelly. Instead of increasing the sensitiveness of the emulsion by holding it at a high temperature for some time, it may be digested at a lower temperature in the presence of ammonia, and not infrequently the silver nitrate is precipitated with ammonia and then re-dissolved in excess before the precipitation of the halide is commenced. The set emulsion is cut up into small portions and is washed in running water in order to remove any excess of halide salts and also the soluble nitrate produced in the reaction. After washing it is given a final digestion and is ready for coating upon the base.

The emulsions used for printing papers are of three general types: bromide papers, which are made with a washed emulsion essentially identical with that used for coating upon glass and film for use in making lantern slides and positive motion pictures; unwashed chloride emulsions in which the emulsion is coated on the paper in the form in which it is mixed without any removal of the soluble salts by washing; and emulsions also made without washing but in which the silver salts are a mixture of chloride and citrate, and in which there is free silver nitrate present, these papers darkening visibly when exposed to light and thus giving a printed-out image which is toned and fixed.

**Coating and Packing.**—Dry plates are coated by passing them on a travelling belt under some device through which the emulsion is allowed to spread out over the surface of the glass. This may take the form, for instance, of a trough with a slit in the bottom or of a stepped weir down which the emulsion flows, reaching the plate by means of a flap which rests lightly on the surface of the plate. The coated glass travels forward on to a belt or rollers which are kept wet with ice-cold water, and there the emulsion sets. At the other end of the machine the plates are taken off, placed on the racks, and dried slowly and evenly. They are then cut to the requisite sizes by means of machines using diamonds and are packed in boxes of one dozen for supply to the market.

Paper is coated by passing from a stock roll around the coating roll which is immersed in about half its depth in a trough of emulsion, the paper as it travels upward carrying the emulsion with it until it passes over a large roll supplied with cold water, which chills the emulsion so that it sets, the setting being completed by passage through a refrigerated box. The coated paper then passes forward to a drying-room in which it is hung up in large loops varying in length from five to 20 ft., the loops travelling down the room continuously by means of a chain and the paper

drying as it travels, so that at the other end the coated and dried paper can be reeled up into a roll. This roll of paper is then cut into sheets, and the sheets stacked on the top of each other are cut by means of guillotines into sheets of the size required for the market, each sheet being inspected for defects before packing.

Film is coated in almost exactly the same way as paper. Film for roll cartridges is coated with gelatine on the back to prevent its curling and is slit to the requisite width and then cut into the lengths required for the cartridges. The film is then spooled on to a core having metal ends so as to protect the edges of the film from light, the film being wound in with black paper or with red paper having an insert of "carbon" paper similar to that used for making duplicates on the typewriter, this type of film being known as *autographic*.

**Film Packs.**—Film is also supplied in film packs, in which the film is cut into sheets of the required size, and to each sheet is attached a tab, the tabs being numbered consecutively. A set of tabs is then assembled into a pack so that as each tab is pulled, the film is removed from the front of the pack, leaving the next film in position for exposure, the tabs being torn off and thrown away.

**Radiographic Film.**—Film of greater thickness, coated with gelatine on the back is used in the flat form in holders similar to those used for plates and thus is cut and packed exactly as plates. For radiography, film is coated on both sides with emulsion, since the X-ray can penetrate the emulsion with very little loss of density. For dental radiography small films are supplied in special packets ready for use without any further protection from the light.

**Motion-picture Film.**—Motion-picture film is slit from the original roll to the exact width required, 35 mm. in the case of standard film, and before packing is perforated on the edges in accordance with the standard gauge used for the cameras and projection machines. Motion-picture film comes on to the market in two general varieties: negative film used in the cameras and positive film on which the pictures are printed and from which they are projected. Negative film is supplied in ordinary and superspeed varieties and also made colour sensitive under the name of "panchromatic" film. Positive film is supplied either on nitrate base, that used most generally, or on acetate safety base, which is slow-burning. For amateur motion-picture photography the film is supplied in the United States and England, 16 mm. in width made on slow-burning acetate base only, and is supplied in lengths of 100 ft. packed with paper leaders at the ends and on a special protective spool so that the cameras can be loaded in daylight. This film is made to be reversed directly to a positive so that the same film as is used in the camera is employed for projection. (G. EA.)

### III. COLOUR PHOTOGRAPHY

The methods which are used at the present time for reproducing objects in colours by photography are dependent upon the suggestion made by Clerk Maxwell. According to Young's theory any colour may be considered to be due to the stimulation of the three primary sensations of red, green and violet. In order to reproduce any colour, therefore, we may analyse the different proportions of these three primary colours in it and then synthesise the colour by superimposing the three primaries upon a screen in projection. To illustrate this, Maxwell took three photographs of a coloured ribbon, one through a red solution, one through a green solution, and a third through a blue solution. From these three negatives, three transparencies were made which were projected each by means of the coloured light by which it was taken, Maxwell adding a fourth picture taken and projected by yellow light.

In 1869 Ducos du Hauron published a small book on colour photography in which he laid down the principles of three-colour photography, on which all later work has been based; and at approximately the same time Charles Cros published an article in which he had independently come to practically the same results. Du Hauron's book is astonishingly complete and contains a very clear account of the two fundamental processes of colour

## LOWER MANHATTAN, NEW YORK CITY

An aerial view of the skyscrapers of lower New York, the financial centre of the city. The tower in the centre background is that of the Woolworth Building (792 ft. high)—except the Eiffel Tower, the tallest structure in the world. The large structure in front of it, the Equitable Building, is 485 ft. high and occupies one entire block. The tower appearing to the left of the latter building and partly hidden by it surmounts the Singer Building (612 ft.

high). In front of the Equitable Building is the pyramid-like tower of the Bankers' Trust (539 ft. high) on the corner of Wall and Broad streets. From the upper right-hand corner of Battery Park (left foreground) runs Bowling Green, a small elliptical area from which Broadway begins and runs northward, although, in the picture, its course is completely hidden by buildings.

(Aerofilms, Ltd.)

#### WESTMINSTER: THE HEADQUARTERS OF THE BRITISH GOVERNMENT

The main thoroughfare in this aerial view of the centre of an Empire is Victoria street, running past Westminster Abbey which can be recognised by its two noble western towers. There England's kings are crowned and her illustrious dead are buried. Victoria street runs into Parliament Square and thence to Westminster Bridge which here crosses the Thames. The group of buildings to the right of the bridge and facing the river is the Houses of Parliament with the Clock Tower containing Big Ben at one end and the Victoria Tower at the other. Almost beneath the Clock Tower is the "Hall of Rufus" or Westminster Hall, where Warren Hastings was impeached. On the left, leading from Parliament Square, is Whitehall, in and around which are the headquarters of the various departments of the British Government. On the other side of the river are St. Thomas's Hospital, facing the Houses of Parliament, and, somewhat to the left, the new headquarters of the London County Council. Behind this can be seen the roof of Waterloo Station, which covers a greater area than any other of the London termini.

photography including their application by different methods. These processes are known as the "additive" (that employed by Maxwell) and the "subtractive" processes.

The practical development of colour photography was, however, delayed for many years by the difficulty that the photographic materials available were sensitive only to the blue and violet of the spectrum; it was with the greatest difficulty that materials sensitive to the visible spectrum could be obtained and with such materials very long exposures were required.

The introduction of colour sensitising by Vogel in 1873 first made colour photography possible, and the introduction of the isocyanine and carbocyanine sensitisers at the beginning of the 20th century made it practical. F. E. Ives was the first to develop Maxwell's process in practical photography. He took photographs through three dyed gelatine filters upon materials sensitised with the best dyes available at that time and projected the transparencies by means of triple lanterns devised for the purpose, these synthetic colour pictures obtained by the additive process giving extremely good colour reproduction upon the screen. He also devised the apparatus known by him as the *Kromskop*, in which the three pictures could be viewed superimposed upon each other and illuminated by light of suitable hue, so that a combined additive image produced by the three colours could be obtained without the use of a projection lantern.

**Principle of the Subtractive Process.**—The "subtractive" process, which was employed by Ives, depends upon the production of colours by subtractive absorption instead of by the addition of the colours to each other in projection. Suppose that over a sheet of yellow gelatine, which will absorb the blue light, is put a sheet of magenta gelatine, which will absorb the green light; then, since the yellow absorbs the blue light, and the magenta the green light, only the red light is transmitted; a red image can thus be obtained either by projecting it through a red filter or by putting a magenta image on the top of a yellow one. In the same way a green image can be obtained by putting a blue-green one on the top of a yellow one, when the yellow will cut the blue out of the blue-green and leave only green.

In working the subtractive process, the three negatives are printed in coloured dyes, the picture taken through the red filter being printed on gelatine dyed blue-green, the one taken through the green filter on gelatine dyed magenta, and the one taken through the blue filter on gelatine that was dyed yellow. Now, if the three are cemented together in register, the resulting transparent colour picture will reproduce the colours of the original subject and will be a transparency which can be viewed in the hand, or examined in front of an artificial light, or projected in a lantern.

**Screen Plate Process.**—In his book, Ducos du Hauron suggested one modification of the additive process which has since become of practical importance and is known as the *screen plate* process. He suggested that the surface of the glass plate or film might be covered with tiny filters—red, green and blue, the sensitive emulsion being coated on top of these and photographed through the filters. This was carried out in practice by Joly, who made plates by ruling alternate lines of red, green and blue-violet by means of a ruling-machine, and later by Lumière, who made the autochrome plates by covering the glass with starch grains dyed in the three primary colours.

In addition to the processes of ruled lines worked out by Joly and by MacDonough in Chicago, and the Lumière process, a process invented by Christensen dependent upon the use of dye particles of dammar emulsified in a suitable liquid has been exploited commercially in Germany, and plates have been made in England by printing the lines in bichromated colloids.

When such colloids as gelatine, fish-glue, etc., are treated with a solution of bichromate, dried and exposed to light, they become insoluble in water. If, then, a glass plate be coated with a solution of bichromated fish-glue, and the coated plate be exposed to light under a black line screen which allows only one-third to be exposed at a time, two-thirds being protected by the black lines, and then washed in water, one-third of the entire surface will be covered by lines of fish-glue, which can be dyed. After the

dye has been mordanted to prevent it running, the plate can be recoated with glue, registered in position on the printing screen, and printed so as to get a second glue line which can be dyed in the second colour, provided that the first line has been protected from the action of the dye by coating it with a varnish or otherwise. The third line can be printed by exposing the plate through the back, when the first two lines will act as a screen for the third, and in this way we can build up a three-colour line screen.

In Germany, Krayn used thin sheets of coloured celluloid of the three primary colours and piled them on top of one another to get a pile of alternate layers of red, green and blue. By cutting sections down through this pile, sheets of celluloid made up of strips of each of these red, green and blue layers were obtained. Screens have also been made by mechanical printing or a combination of this with dyeing, and a number of other methods are possible and have been proposed for making the screens.

All the various processes of colour photography which have been described are applicable to motion-picture work, though, owing to the long exposures required and the loss of light by absorption, no practical process utilising the principle of the screen plate for cinematography has been developed. The motion-picture process, however, like other processes of colour photography, divided clearly into additive and subtractive processes, and, as in the case of the photography of stationary objects, the additive processes developed first.

**Additive Methods.**—In the case of motion pictures, there are two methods of additive synthesis. Either one may project on the screen the three pictures simultaneously, as is done in the triple projection lantern, or the colour units may be projected successively, relying upon persistence of vision for the blending of colours.

**Kinemacolor Process.**—The oldest practical cinematograph colour process is a two-colour process utilising persistence of vision for the addition of the pictures. By means of a rotating disc of colour filters placed in front of the camera, pictures are taken on panchromatic film alternately through a red and green filter, the pictures being taken at twice the normal speed, so that for each complete picture, two negatives are made, one through each filter. The positives from these negatives are projected through a machine, similarly equipped with a rotating shutter, which is made to operate synchronously with the picture, so that the pictures taken through the red filter are again projected through a red filter, and the green pictures similarly through a green filter. The succession of red and green pictures upon the screen produces complete synthesis by persistence of vision and gives the effect of a two-colour additive picture. This process is known as the *Kinemacolor* process and enjoyed a considerable success.

**The Gaumont Process.**—The most complete and satisfactory process of colour cinematography is undoubtedly the simultaneous three-colour additive process worked out in its complete form by Gaumont. Three lenses are used in the camera, and three pictures are taken through the primary colour filters upon the same strip of film. The positives are projected in a machine fitted with a corresponding pull down and gate, and with three condensers and three sets of objectives fitted with special registering devices. The results given by this process are admirable.

**The Subtractive Process.**—An advantage of the subtractive colour process is that the film so produced can be shown in any ordinary machine, and this advantage is even greater in the case of motion pictures than in the case of ordinary lantern slides. The obvious method of making subtractive motion pictures would be to make three negatives and to superpose the negatives upon each other in printing, recoating the film each time and using a dyed bichromatic process or a process in which the silver image is made to mordant the dye and so is transformed into a colour image. The recoating and re-registering, however, present very great difficulties in practice and would make the process very costly. The practical subtractive processes of colour cinematography use only two colours: these two colours may be either in the one emulsion layer, or in two emulsion layers on

opposite sides of double-coated film, a method which appears at the present time to offer considerable advantages in the direction of simplicity.

It is clear that since there are two sides to a film, it is possible to coat an emulsion on each side of the film and to print the red image on one side and the green on the other. This process has been worked out to a practical end in several ways, some of the colour images being produced by the mordanting of a dye upon an image obtained by the conversion of the silver into some suitable substance or by the imbibition of a dye into the gelatine or by toning by chemical means to coloured images.

**Prizma Process.**—Of the two-colour subtractive processes, the Prizma process, depending on the use of mordanted images, was successful for a number of years. This is a typical two-colour process, the red and green negatives being printed on opposite sides of double-coated film and the coloured images produced by mordanting dyes on to images obtained by replacement of the original silver image by materials capable of mordanting the dye.

**Technicolor Process.**—In the Technicolor process, the images on opposite sides of the film are gelatine reliefs prepared by printing through the back of thin films and then cementing the two films back to back, developing, bleaching and washing away the gelatine which during bleaching has been left soft as a result of the absence of an image. The gelatine relief so obtained is coloured with suitable dyes.

**Kodachrome Process.**—In the Kodachrome process positives are printed from the original negatives and these are printed on opposite sides of double-coated film to produce negative images. These silver images are removed by a solution which renders the gelatine impermeable where the silver grains were acted on by the solution. After fixing, washing and drying, the film is dyed on both sides in the appropriate colours, the dyes penetrating the permeable gelatine only where no negative image was present and thus producing a positive image consisting of pure dye.

#### IV. GENERAL PRINCIPLES

Modern photographic emulsions consist of a precipitate in gelatine of flat crystals of silver bromide, generally hexagonal or triangular in shape. These crystals have a cubic lattice, and the addition of iodide to the emulsion produces crystals in which the iodine replaces bromine directly in the lattice, and slightly increases the lattice spacing. The distribution of different sizes of crystals depends upon the method by which the emulsion is produced, and the properties of the emulsion depend upon that distribution (see fig. 1). The silver halide grains act as units both toward light and toward the action of the developer, so

that each individual grain acted upon by light becomes developable when a sufficient amount of action has taken place, and it will be completely reduced by the developer; but the exposure of one grain will not affect any other grain unless the chemical action of development can spread by contact from one to the other (see fig. 2).

If we suppose that the same amount of photo-chemical product (latent image) makes either a large or a small grain developable, then, other things being equal, the larger grain contributes a larger amount of silver to the image and thus gives more density for the same amount of light action than a smaller grain. For this reason alone, emulsions containing large grains would be more sensitive than those containing small grains, but experiment has shown that this is not the only factor and that larger grains require less light action to become developable than small grains. Further it has been shown that the seat of this sensitiveness is concentrated in specks in the grains, and the sensitiveness of the grain depends upon the presence and the number of these sensitive specks.

Being different in nature from the silver bromide itself, it was suspected that the specks were derived from the gelatine, since some gelatines give emulsions which are much more sensitive than others. A material was extracted from gelatine which was identified by Dr. S. E. Sheppard with allyl mustard oil, which in ammoniacal solution becomes allyl thiocarbamide. Allyl thiocarbamide reacts with silver bromide, and the compound of the two in alkaline solution produces silver sulphide, so that the sensitising specks may be ascribed to the presence of minute traces of silver sulphide on the surface of the silver bromide grain. The ripening process characteristic of the preparation of gelatine bromide emulsions may be ascribed partly to the development of grains of larger sizes from those of small dimensions and partly to the production of the sensitising specks of silver sulphide on the surface of the grain.

The exact action of light upon the grains is not well understood, though much research work is being done on the subject. For a discussion of the various theories which have been proposed, the literature must be consulted.

The photographic properties of an emulsion are expressed by its characteristic curve, the present form of which was originally suggested by Hurter and Driffield. In this curve, which is shown in fig. 3, the density is plotted against the logarithm of the exposure. The density is the logarithm of the reciprocal of the transparency ( $D = \log 1/T$ ) and has been shown experimentally to be proportional to the mass of the silver per unit area. The amount of silver which will produce a density of unity, corresponding to a transmission of  $1/10$ th of the incident light, is

## PHOTOGRAPHY, COLOUR

Three examples of direct colour photography. The top left-hand view is from a snapshot taken at 6.0. a. m. (Photographs by H. A. Key.)

termed the "photometric constant." For ordinary photographic emulsions about 10 milligrammes of silver will produce a density of unity on one square decimetre of surface. The curve obtained by plotting the density against the logarithm of the exposure shows three fairly well-defined regions: the initial part, convex to the  $\log E$  axis, termed the region of *under-exposure*; the middle part, which approximates to a straight line, termed the region

graphic printing and reproduction later; meanwhile, we may note that the straight-line portion of the characteristic curve can be represented by the equation,

$$D = \gamma (\log_{10} E - \log_{10} i)$$

where  $E$  is the exposure (intensity of light  $\times$  time) to light,  $\gamma$  is the development factor, i.e.,  $\tan \theta$  in fig. 3, and  $i$  is a constant,

FIG. 3.—Hurter and Driffield curve. The density of the negative plotted against the logarithm of the exposure to show the characteristics of the emulsion.

the exposure at which the straight line cuts the axis. Although this equation can be regarded as only an approximation, it is a very useful one, furnishing a reference standard for the phenomena of both development and exposure. It will be seen that as long as this equation holds for different degrees of development  $D = k\gamma$ ,  $E$  being constant, that is, any function representing change of density with degree of development will be true also for  $\gamma$ . This is expressed in Hurter and Driffield's Law of Constant Density Ratios. The normal manner in which the density and gamma change with time of development, if this law holds, is represented in fig. 4.

FIG. 4.—Change of density and gamma with time of development. As the time of development is increased, density and gamma increase.

The characteristic curves intersect at a point ( $\log_{10} i$ ) on the  $\log_{10} E$ -axis. The value of  $\gamma$  increases with time of development, but less and less as development proceeds, and ultimately reaches a limit which is characteristic of the plate but also depends to some extent on the developer. If we now develop (for different times) plates which have been given a series of exposures increasing in geometric proportion, measure the densities and plot the

FIG. 2.—Undeveloped and developed silver grains. The undeveloped silver bromide crystals are transformed into amorphous black grains of metallic silver.

of *correct exposure*; and the upper part, concave to the exposure axis, termed the region of *over-exposure*. If we prolong the straight line portion to cut the exposure axis at a point  $I$  (this was termed by Hurter and Driffield [fig. 3], the *inertia of the material*) and the reciprocal of the inertia is taken as a measure of the sensitiveness of the material, the slope of the straight line portion, that is, the tangent of the angle  $\theta$ , is termed the *development factor*, known in photography as  $\gamma$ .

The value of  $\gamma$  increases with time of development, the increase tending to a limit termed  $\gamma_{\infty}$  (gamma infinity), which measures the extreme contrast of which a plate is capable. We shall return to the significance of these quantities for photo-

resulting curves and then plot  $\gamma$  (or density  $D$ ) as a function of time, we get a curve of the type shown in fig. 5. It will be seen that  $\gamma$  (and density) increase rapidly at first, then more slowly, finally reaching a limit.

Making certain simplifying assumptions, the mathematical function representing this curve can be obtained. Let us suppose,

Fig. 5.— $\gamma t$  curve. Growth of  $\gamma$  with increasing time of development.

in agreement with the approach of the curve to a limit, that  $D^\infty$ , the limiting density, corresponds to the total developable silver bromide for any fixed exposure. The density undeveloped at any time  $t$  will be  $D^\infty - D$ , where  $D$  is the density developed at time  $t$ . Supposing other factors—such as the concentration of the developer in the film, its rate of diffusion, temperature, etc.—

constant, we can then put the rate of development,  $\frac{dD}{dt}$ , pro-

portional to the undeveloped density i.e.,  $\frac{dD}{dt} = k (D^\infty - D)$ , where  $k$  is a constant. This equation gives on integration

$$k = \frac{1}{t} \log_e \frac{D^\infty}{D^\infty - D} = \frac{1}{t} \log_e \frac{\gamma^\infty}{\gamma^\infty - \gamma} \quad \text{or } D = D^\infty (1 - e^{-kt}); \gamma = \gamma^\infty (1 - e^{-kt})$$

The constant  $k$  is termed the velocity-constant of development.

When bromide is present in a developer, the straight line portions of the characteristic curve when produced do not meet

Fig. 6.—Bromide depression curve. Bromide in the developer causes a depression of the convergence point.

upon the exposure axis but at a point somewhat below it, the effect of bromide being equivalent to a constant depression of density in the straight line portion of the curve (see fig. 6). This depression of the intersection point shown as  $b$  can be used for evaluating the action of bromide, and since an inverse functional relation exists between the reduction potential of the developer

and the bromide concentration which will produce a given depression of the intersection point, a scale can be obtained expressing the relative energies of developers. The following table from A. Nietz gives what are probably the most reliable data.

|                                                | Relative Energy |
|------------------------------------------------|-----------------|
| ferrous oxalate                                | 0.3             |
| p-phenylene diamine, hydrochloride (no alkali) | 0.3             |
| p-phenylene diamine hydrochloride (alkali)     | 0.4             |
| hydroquinone                                   | (standard) 1.0  |
| p-phenyl glycine                               | 1.6             |
| hydroxylamine                                  | 2.0             |
| toluhydroquinone                               | 2.2             |
| p-aminophenol (hydrochloride)                  | 6.0             |
| chlorhydroquinone                              | 7.0             |
| dimethyl p-aminophenol (sulphate)              | 10.0            |
| monomethyl                                     | 20.0            |
| diamidophenol                                  | 30.40           |

Since the inertia is expressed in exposure units (m.c.s.) its numerical value depends upon the light source employed in the measurement of the characteristic curve. Hurter and Driffield used originally the standard candle and then a pentane lamp; at the present time electric-light sources and acetylene burners are employed. The International Congress of Photography in 1925 recommended as the standard light source for photographic work the adoption of one visual candle-power of light of colour

Fig. 7.—Characteristic curves of papers with increasing times of development. Increasing time of development produces regression of inertia without affecting  $\gamma$  except during induction period.

temperature 2,360° absolute. Many workers prefer to use a light which has been modified by passage through a filter which is reducing its quality approximately to that of sunlight, corresponding to a colour temperature of approximately 5,000° absolute. The so-called "H & D" speeds of photographic materials thus depend entirely upon the light source and other conditions used in testing, and the speeds given by one maker are not comparable on casual inspection with those from another source.

The photographic characteristics of printing papers can be measured by a procedure similar to that used for negative materials, but in this case it is not the mass of reduced silver which is of chief importance but its relative reflecting power. The reflection density is thus the logarithm of the reciprocal of the reflecting power ( $D = \log_{10} 1/R$ ), the reflecting power being measured with illumination at 45° to the plane of the paper. The characteristic curve obtained with different times of development is shown in fig. 7, and it will be seen that the effect of increase in time of development is to produce a regression of the inertia without change in  $\gamma$  except in the very earliest stages, where the curves are usually of a distorted form. The following constants may be derived:—

| Constant                                  | Symbol                  | Significance                                                   |
|-------------------------------------------|-------------------------|----------------------------------------------------------------|
| (a) Maximum (reflection density)          | $D_{\max}$              | Highest attainable density.                                    |
| (b) Contrast element (reflection density) | $\frac{dD}{d \log_e I}$ | Differential.                                                  |
| (c) Gamma element (reflection density)    | $\gamma$                | Value of (b) for straight-line portion, or at inflexion-point. |

| Constant                                   | Symbol | Significance                                                                   |
|--------------------------------------------|--------|--------------------------------------------------------------------------------|
| (d) Latitude element (reflection density)  | L      | Range of intensities reproduced on straight-line portion.                      |
| (e) Rendering power (reflection density)   | R      | $\frac{10L}{S}$                                                                |
| (f) Total scale (reflection density)       | S      | Range of intensities reproducible by density differences.                      |
| (g) Standard exposure (reflection density) | Es     | The exposure in m. c. s. necessary to print through a negative density of 2.0. |

From a study of the characteristic curves of the materials used in making the negative and of the material used for printing the negative, the reproduction of the tones of the original subject in the photograph may be traced. By "tone" is understood the variation from light to shade in the subject or the gradation of luminosity apart from colour. This problem is the central one of photographic theory and is fundamental to practically every application. Physical tone may be taken as equivalent to light intensity or photometric brightness, whether this be intrinsic or reflected. Physiologically, it is apparent brightness that matters, and this can conveniently be treated as physical brightness modified and interpreted by the human eye.

The physical range of tones in a subject may be determined photometrically. In ordinary landscapes a range up to 1 to 10 is low; 1 to 30 or 1 to 40 is a normal contrast; 1 to 60 and upwards, high; 1 to 250, extreme. The limits of correct rendering are fixed by the straight-line portions of the characteristic curves. For methods of computing the tone reproduction given in any photographic operation, the papers by F. F. Renwick and L. A. Jones must be consulted.

The resolving power of photographic materials may be defined as the distance between two closely adjacent images which can just be distinguished. It is limited primarily by what is termed the irradiation or spreading of the image due to diffusion of the light in the film. This spreading of the image has been investigated by astronomers and used as a basis for a method of stellar photometry.

In addition to the irradiation factor, the resolving power depends upon the development factor attainable in the material. The sharpness of an image, in fact, is theoretically equal to the development factor divided by the turbidity factor. Both of these factors are functions of the wave-length of the light used in exposure, so that the resolving power is naturally dependent upon the colour of the light. In addition to these two factors, a psychological factor enters into resolution dependent upon the graininess of the image.

Photographic images on development show with lower power magnification, as used in projection and enlarging, a granulation which is objectionable in such operations. L. A. Jones and N. Deisch have shown that it may be measured and numerically expressed on the assumption that  $G$ , the graininess, is directly proportional to the distance at which it becomes just visually imperceptible, this being compared with the distance at which a structure of known period, e.g., a fine cross-line screen, just disappears. Suppose a screen of 2,000 lines to the inch to be equivalent in this way to a given granularity of the developed image, the latter may be said to have a graininess of 2,000.

FIG. 8.—Fan test object, used for measuring the resolving power of photographic materials.

The practical resolving power of photographic materials can be measured by photographing the reduced image of a fan-shaped black and white grating (see fig. 8) and measuring the extent to which the lines are resolved.

**Colour Sensitiveness.**—Silver bromo-iodide materials are sensitive to the ultra-violet, violet and blue of the spectrum, the limit of sensitivity in the green being at about  $550 \mu$ . Recent investigations in which the sensitivity has been plotted against wave-length for equal amounts of energy show as far as measurements have yet been made that the sensitivity rises to a maximum at about  $480 \mu$ , in the case of materials of high sensitiveness and is constant throughout the violet and ultra-violet. When the spectrum below  $\lambda 300$  is photographed, the absorption by the gelatine becomes important, and below  $\lambda 200$  ordinary photographic materials are practically useless. Schumann suggested the use of plates made without any gelatine, silver bromide being precipitated and allowed to settle at the bottom of a deep dish on to glass plates. A method which has been used recently for the photography of the short wave-length ultra-violet is a fluorescent coating of mineral oil which transforms the short

FIG. 9.—Spectra of ordinary, ortho and panchromatic materials, taken in a diffraction grating spectrograph in front of the slit of which is placed a black grass wedge

ultra-violet waves into blue light and these produce an effect upon the plate.

The sensitising effect of dyes discovered by Vogel has been developed very greatly. Erythrosine, that is the tetra-iodo derivative of fluorescein, was found by Eder to be the most suitable dye for sensitising in the green and yellow and has been adopted by photographic manufacturers throughout the world, the materials so sensitised being known as *orthochromatic* materials. In fig. 9 are shown the spectra of an ordinary material, an orthochromatic one made by the use of Erythrosine, and a panchromatic one made by the use of the dyes introduced by the Hoechst Dye Works soon after 1900.

A new period in the development of the sensitivity of photographic materials arose with the discovery of the sensitising power of Ethyl Red by Miethe and Traube in 1902, Ethyl Red being a dye produced by Spalteholz in 1883 by the combination of quinaldine ethiodide with quinoline ethiodide in the presence of alkali. E. Koenig at the Hoechst Dye Works introduced several dyes analogous to Ethyl Red which are known as the *isocyanines*; and in 1906 Homolka produced another class of dyes now known as the *carbocyanines* by effecting the condensation in the presence of formaldehyde, the first of these dyes to be introduced being Pinacyanol. By the use of Pinacyanol, generally in combination with some of the isocyanine dyes, materials are rendered *panchromatic*; that is, sensitive to the whole visible spectrum up to and including the red. Soon after

the introduction of Pinacyanol, the Hoechst Dye Works introduced Dicyanine, which sensitises far out into the infra-red but is difficult to use. It has, however, been employed with success for the photography of spectra up to  $\lambda 900$ . In 1919 Adams and Haller discovered a new dye, Kryptocyanine, with its maximum sensitiveness at  $\lambda 760$ , and this dye makes it possible to take photographs by infra-red light with a very short exposure; it is employed even for motion-picture photography. A new dye discovered by H. T. Clarke in 1925 makes it possible to photograph the spectrum without difficulty up to  $\lambda 900$ , the maximum sensitiveness of this dye being at  $\lambda 820$ . (C. E. K. M.)

**PHOTOSYNTHESIS** (see 21.748).—The term photosynthesis is very commonly applied to the process by which green plants build up organic food material under the action of light. It is not altogether a satisfactory term, for as the literal meaning is "synthesis under the action of light" it would include any chemical synthetic process of this type. Also it is not at all certain that the actual *synthetic* process is due to the action of light. The term carbon-assimilation is also employed though it carries with it the suggestion that carbon itself rather than carbon dioxide is assimilated. The expression "photosynthetic assimilation of carbon dioxide" is probably the most accurate description. During recent years there has been a very large output of work on this branch of plant physiology and the field is a very wide one. The subject has been admirably reviewed by Stiles.<sup>1</sup>

**Pigments.**—The process of photosynthesis in plants is associated with certain pigments which absorb the incident light; the energy so obtained is employed in the building up of complex organic substances from carbon dioxide and water, oxygen being at the same time evolved. It should be realised that the whole life of the globe is dependent on the photosynthetic power of green plants; they alone are able to manufacture their own food material. Non-green plants and animals have not this power, but are entirely dependent for their food on the green plant. In the case of the higher plants, the pigments of the green leaf, as we know mainly from the work of Willstätter and his collaborators,<sup>2</sup> are four in number — *Chlorophyll a*,  $C_{55}H_{72}O_5N_4Mg$ , a blue-black crystalline substance, greenish blue in solution; *Chlorophyll b*,  $C_{55}H_{70}O_5N_4Mg$ , a green-black substance, green in solution; *Carotin*,  $C_{40}H_{56}$ , an orange-red substance found also in carrots, and *Xanthophyll*,  $C_{40}H_{58}O_2$ , a yellow substance. The two first are the green pigments and are often termed "chlorophyll," the other two are the yellow pigments. The amounts of these do not vary very greatly in different leaves. The average amounts are given below:—

|               | Percent of Fresh Weight | Percent of Dry Weight |
|---------------|-------------------------|-----------------------|
| Chlorophyll a | 0.2                     | 0.63                  |
| Chlorophyll b | 0.075                   | 0.24                  |
| Carotin       | 0.017                   | 0.05                  |
| Xanthophyll   | 0.033                   | 0.09                  |

In green algae the same four pigments are present; in the brown and red algae and blue-green algae chlorophyll is present in association with other pigments which give these plants their peculiar colour. The assimilating pigments are not dissolved generally in the cell but are associated with denser portions of the protoplasm of definite form, known as plastids; it is apparently in these plastids that the special physical and chemical processes characteristic of photosynthesis occur. It is generally accepted that the two green pigments are the most important in the process of photosynthesis. One of the functions of the green pigments is clearly that of absorbing the necessary energy for the decomposition of carbon dioxide, and their solutions show very characteristic absorption bands particularly in the red-orange and the violet end of the spectrum. Whether in addition the chlorophyll reacts chemically with the carbon dioxide is still in doubt. Willstätter and Stoll<sup>3</sup> hold that the carbon dioxide combines with the chlorophyll to form a definite compound on which light acts; it is thus converted into a substance of the nature of a peroxide which can be acted upon by an enzyme.

Warburg<sup>4</sup> holds that by the action of light upon the chlorophyll there is formed oxygen and a "photochemical primary product," which then reacts with a derivative of carbon dioxide; this derivative, the "acceptor" is reduced, and the chlorophyll is reformed.

**Products of Photosynthesis.**—Sachs (1862) was the first to relate the carbohydrates appearing in the leaf to the process of assimilation; he was responsible for the dictum that starch was the "first visible product of assimilation." This was based on the fact that in the case of many plants it appeared in the plastids of the leaf in the light and disappeared again in the dark. It is now generally agreed that carbohydrates of some kind are the main products of photosynthesis though many monocotyledons form little or no starch, but much sugar in the form of glucose, fructose and cane sugar. Which carbohydrate is first formed is a matter still in dispute. In green leaves exposed to light cane sugar accumulates markedly, and this has led to the view that it is the first-formed sugar. A much more plausible hypothesis would seem to be that hexose sugars (glucose and fructose) are first produced, and that when these reach a certain concentration cane sugar is formed from them. This view is supported by the work of Weevers.<sup>5</sup> The starch arises in all probability from glucose; it would seem likely that there is a critical concentration of sugar in the chloroplast above which starch is formed from the sugar, and below which the starch is converted back into sugar. This is confirmed by the fact that by floating them on sugars of high concentration such leaves as are normally starch-free will produce that substance in their chloroplasts.

**Formaldehyde Hypothesis.**—Baeyer in 1870 put forward the suggestion that in the process of photosynthesis formaldehyde ( $CH_2O$ ) is produced with the help of chlorophyll under the action of light, and that the formaldehyde then polymerises to form sugar. Since that time the view that formaldehyde is an intermediate product in photosynthesis has been very commonly held. Although formaldehyde can be produced from carbon dioxide and water under certain conditions and hexose sugars can arise from it, yet there is no clear evidence of the presence of formaldehyde in the green leaf. The formaldehyde theory, though attractive in its simplicity, cannot be said to rest on any very secure foundation.

**Effect of Various Conditions on the Rate of Photosynthesis.**—The rate of this process is affected by the concentration of carbon dioxide available, by the amount of water, by the intensity of the light and by its wave length, by the chlorophyll content, by the supply of oxygen and of mineral salts and also by many other internal conditions, or factors as they are called. It used to be supposed that all these factors acted independently, but it was shown by the work of F. F. Blackman<sup>6</sup> that the factors are closely inter-related. He put forward the "theory of limiting factors," that in any set of conditions the rate of the process was determined by the factor present in the lowest intensity. The view that under any set of conditions it was only by the increase of the intensity of one factor that the rate of process could be increased requires some modification in the light of recent work; it is clear, however, that if any factor A is present at very low intensity, it will prevent an increase of another factor B having the marked effect upon the rate of the process which it would have produced if the factor A were acting at a higher intensity.

Bearing this relationship of the factors in mind, we find that with increasing concentration of carbon dioxide the rate of assimilation goes up proportionally, if the concentration is not too high and light and temperature are sufficient. Similarly with increasing light-intensity the rate of assimilation goes up proportionally if the temperature and concentration of carbon dioxide are sufficient. With higher light intensities there is probably a falling off in the rate, as with higher concentrations of carbon dioxide. With a moderate temperature, if other conditions are favourable, the rate of assimilation obeys the Van't Hoff rule, approximately doubling for each rise of temperature of  $10^\circ C$ . At higher temperatures somewhere in the neighbourhood of  $25^\circ C$ ., the injurious effect of high temperature appears and the rate begins to fall off. The process of assimilation

is little sensitive to the concentration of oxygen, reduction to 1-100th of the normal amount having no effect but complete absence of oxygen acts injuriously.

A number of internal factors must markedly affect the rate of photosynthesis, but the only one that has been closely investigated (by Willstätter and Stoll) is that of the chlorophyll-content. It was found that the photosynthetic rate per unit of chlorophyll (the "assimilation number") varied markedly in different plants and even in the same plant. Leaves of yellow varieties were found to show very high rates in proportion to the amount of chlorophyll present, though the rate in these leaves is less influenced by temperature than is that of fully green leaves. Clearly there is some internal factor (or factors) other than chlorophyll content which is controlling the rate. This may be termed the "protoplasmic factor." Willstätter and Stoll conclude that the factor is an enzyme. A reduction in the water content of the leaf has also been shown to be associated with a certain amount of reduction in the rate of photosynthesis.

*Effect of Quality of Light on Photosynthesis.*—The question of the effectiveness in photosynthesis of light of different wave lengths has been hotly debated by physiologists for many years. The question is a complicated one since in white light there are great differences in the energy-value of the rays of different wave lengths, and the different rays are absorbed to a very different degree by the chlorophyll and the colourless parts of the leaf. In the case of the leaf there is little doubt that with equal intensity of incident light the red rays are more effective than the blue. The work of Warburg and Negelein quoted below indicates also that for equal quantities of light energy absorbed by the chloroplast, the red rays are considerably more effective than the blue.

*Efficiency of the Photosynthetic Process.*—It is known that the green leaf is comparatively inefficient as a producer of assimilation material. Brown and Escombe<sup>7</sup> attempted to determine the efficiency of the green leaf by comparing the energy of the light absorbed with the absorption of carbon dioxide, the assumption being made that glucose was produced in the leaf from the carbon dioxide. Their results are only very approximate but they indicate that the efficiency is only about 1%, increasing however with low intensities of light to about 4%. A large proportion of the energy absorbed is used in transpiration, and with the higher intensities of light the concentration of carbon dioxide is too low to allow of the light being fully effective. The most accurate experiments on the efficiency of the photosynthetic process are those of Warburg and Negelein<sup>8</sup> with the unicellular alga, *Chlorella*. With such a plant there is no question of transpiration, and the experimental arrangements were such that practically the whole of the light received was absorbed by the chloroplasts of the cells; in the case of the leaf a considerable amount of the light passes through and a certain amount is reflected.

Warburg and Negelein show that with decrease in the intensity of the light the efficiency goes up, i.e., a larger proportion of the light absorbed is made use of in photosynthesis, the rate of the latter process being measured by the production of oxygen. In their earlier experiments they obtained an efficiency of 71% when using yellow and yellow-red rays; the methods employed for calculating this were, however, not altogether satisfactory. In their later work they obtained results of 50% for red light, and 34% for blue light. Whether these percentages are the maxima that can be obtained is not yet certain; internal factors may have been present which reduced the rate. The results do show, however, that under these special conditions (carbon dioxide 4%, temperature 10° C. and a very low intensity of red light) the photosynthetic process in the green plant may exhibit a higher level of efficiency than that of any photochemical process studied in the laboratory. The apparent inefficiency of the green leaf is no doubt largely due to the fact that much of the energy of the light is used in transpiration and also to the fact that there is a large amount of absorption by structures in the leaf other than the chloroplasts.

**PHOTOTELEGRAPHY.**—The problem of transmitting diagrams, pictures and particularly photographs, has engaged the attention of communication engineers since the earliest days of the telegraphic art. It has, however, only been within the last few years that practical success has been achieved, leading to the inauguration of regular commercial picture transmission services on established communication systems.

*Elements of the Problem.*—The problem of transmitting pictures to a distance may be considered as divided into five steps. The first step is to analyse the picture into its elements, or to scan it. The second step is to provide means for translating the variations of light and shade of the picture into transmittable signals—for instance, electrical impulses or variations of current strength. The third step is to provide a transmitting system such as wires for carrying electrical current, capable of faithfully conveying the signals to a distant point. The fourth step consists in retranslating the transmitted signals into various values of light and shade. The fifth step is provision for some means of synchronisation, that is, of assuring that the recombination of the transmitted signals places the received picture elements in their proper relative positions.

*Analysing or Scanning Means.*—Any picture may be resolved into small elements, each of uniform tone value. The problem of analysing the picture for transmission purposes consists in running over or scanning each of the minute elements of the picture in some regular manner. Several different devices have been suggested and used for this purpose. Prominent among these are cylinders on which the picture, usually in transparent form, as for instance on a celluloid film, is wrapped. The analysing point, such as a stylus or a small spot of light, is located at a fixed point in relation to the apparatus and the cylinder is given a screw motion about its axis whereby every point of the picture is in turn passed over the analysing point. Other devices used, where the picture signal is initiated by the action of light, employ mirrors and prisms. A frequently suggested device consists of two mirrors arranged to oscillate about axes at right angles to each other—one mirror scanning the picture in a right and left direction, and the other in an up and down direction. For the same purpose, prisms of variable angle have been used, whereby the spot of light or an image of the picture is oscillated in two directions.

*Translation of Picture Tone Values into Electrical Current Variations.*—The most primitive method of going over from the light and shade of a picture to variations of electric current consists in the division of the picture into small elements, and the estimation or measurement of the average tone value of each such element. This estimate or measurement may then be transmitted as a number or symbol in a code, for subsequent interpretation at the receiving end. A later development was to produce the translation by means of a photographic relief, such for instance as a bichromated gelatine photograph, in which the different lights and shades of the pictures are represented by different elevations. Another development of the same idea is embodied in the production of a line or dot picture of the "half tone" type in which the various shades are reproduced as lines of variable width suitable for the production of electrical contacts of varying duration. The more modern forms of picture transmission apparatus employ photo-sensitive devices, such as light sensitive resistances (e.g., selenium *q.v.*) or photoelectric cells. These devices vary the strength of an electric current in more or less approximation to the strength of the light. Selenium cells and similar devices which figured prominently in earlier suggestions of this sort are unsatisfactory because their response to light variations is non-proportional and is subject

to considerable lag. The alkali metal photoelectric cell is the most satisfactory form of light-sensitive device as its response is proportional to the intensity of the light and is instantaneous. The currents furnished are, however, quite small, and the practical application of photoelectric cells was delayed until the development of the vacuum tube amplifier, by means of which the photoelectric cell currents may be amplified to a value suitable for use on commercial transmission lines.

The electrical signals derived from any of the methods mentioned for translating light and shade into electrical current variations may be applied directly to a transmission line or may be used to make an intermediate record, such as a perforated tape of the kind used in telegraphy. The use of an intermediate record of this sort possesses advantages where the character of the transmission line is such that the order of a succession of signals may be differentiated while their intensity is difficult to retain.

**Transmission.**—In the present state of the communication art, it is essential that the picture signals should be of such intensity and quality that they may be transmitted over existing communication systems. Such systems may be submarine telegraph cable, wire telephone or telegraph, or radio telephone or telegraph. The greatest success has thus far been achieved on wire lines because of their relative freedom from static variations of transmission level, and interference in general. Given a picture-transmitting apparatus which provides signals of a sort appropriate for existing transmission lines, the transmission of pictures becomes a problem differing little from the transmission of telegraph or telephone currents, requiring, however, a high degree of constancy and freedom from interference, because of the permanent injury done to a picture by any disturbances, however brief, occurring during its transmission (see TELEPHONY).

**Translation of Electric Signals into a Picture.**—The signals received over the transmission line may be retranslated into values of light and shade by any one of several methods. The various tones may be reproduced by variable sized structures, as in the half tone process, by the use of a pen under varying pressure, or by the use of dots of various sizes produced by a printing device, such as a typewriter controlled by the incoming signals. The picture tones may also be reproduced by fixed-sized areas of different density, as by a controlled air brush, or by chemical action induced by the current, or by varied exposure of a photographic sensitive surface. Variation of the exposure of a photographic sensitive surface may be accomplished by passing the variable incoming picture current through a light-producing device, such as an incandescent filament or a vacuum tube lamp, or by varying an opening through which light is incident on the film. Devices of the latter type are called "light valves." They consist in general of strings or ribbons positioned in front of small apertures and of such small mass as to vibrate with satisfactory amplitude when actuated by the picture signals.

**Synchronisation.**—The accurate synchronisation of the sending and receiving ends may be accomplished by some form of clocks at the two ends, kept at identical rates by the occasional transmission of synchronising signals. Synchronisation may also be accomplished by sending signals during the transmission of the pictures. These may either be sent at those times when the scanning device temporarily passes off the edge of the picture, bringing the apparatus at the two ends into step, or they may be sent continuously during the process of transmission. In the latter case the synchronising signals must be transmitted over a channel separate from the picture channel.

**Practical Processes.**—Picture transmission over communication lines of short length has been accomplished during the past 25 or 30 years by various experimenters, among whom may be noted Korn, Amstutz, Thorne Baker and Belin. Recent systems, which have been worked out for use on modern communication channels, include the "Telepix," the Bartlane, and the system of the American Telephone and Telegraph Co., the latter now in commercial operation between some of the principal cities of the United States. In this system the picture to be transmitted is put in the form of a positive photographic print on celluloid

film. This is placed on a transparent cylinder which is advanced and rotated by a screw motion. A minute spot of light is focused on the surface of the film and passes through it on to an

FIG. 1.—Schematic diagram of sending end apparatus for transmission of pictures by the American Telephone and Telegraph Company system. The picture to be sent is in the form of a celluloid film transparency, wrapped around a transparent cylinder. A beam of light passes through the film and falls on a photoelectric cell. The electric current thus produced is amplified by vacuum tube amplifiers, and is used to modulate a voice frequency alternating current, produced by a vacuum tube oscillator. The entire picture is scanned by advancing and rotating the transparent cylinder by a screw motion, the motive power being furnished by an impulse motor controlled by a tuning fork. The fork also acts as a modulator for low frequency alternating current to be sent to the receiving end to control the speed of the receiving cylinder. Both picture and speed control signals go on the same pair of wires.

alkali metal photoelectric cell. The current from the photoelectric cell is amplified and then used to "modulate" or vary the strength of a "carrier" alternating current of voice frequency suitable for efficient transmission over telephone lines (see fig. 1). At the receiving end, the incoming current operates a light valve (see fig. 2) the light from which falls on a sensitive photographic film moved in synchronism with the film at the sending end. The transmission of a 5-in. by 7-in. picture built up of adjacent strips  $1/100$  in. in width is completed in about seven minutes. Synchronism of the sending and receiving ends is secured by transmitting low frequency impulses from a tuning fork to impulse motors at the two ends. The synchronising pulses are transmitted on a carrier frequency lower than that used for the picture, and the two different carrier currents (of approximately 1,300 and 400 cycles per second frequency), which go over a single pair

FIG. 2.—Details of a "light valve," used in apparatus for receiving electrically transmitted pictures.  $r$  is a fine ribbon of electrically conducting material, through which the incoming current flows. The ribbon stands in a magnetic field produced by an electro-magnet, one of whose pole pieces is shown at  $p$ . The pole pieces are pierced by a narrow hole, through which passes a beam of light whose size is limited by he adjustable jaws  $j$ . When current flows through  $r$ , the ribbon is deflected to one side by an amount proportional to the current, thus permitting the beam of light to fall on a photographic sensitive film, which is being moved in exact synchronism with the picture at the sending end.

of wires, are separated from each other at the receiving end by electrical filters (see fig. 3). The system is adapted for the transmission of all kinds of pictures and diagrams. News photographs form a considerable part of the traffic, but finger prints, mechanical drawings, advertising material, autograph signatures, etc., are also transmitted.

The system just described is capable of use not only on wire circuits, but on wireless circuits. These latter are, however, inherently less stable and are used only where wire channels are not available. Other systems using radio for picture transmis-

**PHYSICAL CHEMISTRY** (see 6.65).—This is the branch of science which unites physics and chemistry. Whilst chemistry was originally occupied by the changes which matter undergoes in composition, classical physics describes the properties of relatively few substances, the materials, as far as composition is concerned, remaining constant during a physical change. The progress of knowledge led to a more intense study of chemical properties, and attempts were made to express the laws of chemical change in mathematical terms. On the other hand, physics investigated an increasing number of chemically individual substances, and the department of physical chemistry developed, covering the ground where the two sciences overlapped one another.

#### HISTORY OF THE SCIENCE

In the early days of science, chemistry and physics were not differentiated. Later, the great progress of physics and the discoveries of Newton accelerated the search for the laws governing chemical processes. Perhaps the greatest interest was aroused by the case of solution, which lies on the border between physics and chemistry. Newton even tried to apply the theory of gravitation to this phenomenon, maintaining that a salt is dissolved in water if the particles of salt have a greater attraction for water molecules than they have for one another. Newton found that such interaction gave an insufficient explanation, and repulsion is responsible for the distribution of dissolved molecules in a solvent. In a certain sense he hereby introduced the idea of osmotic pressure, which plays an important part in modern theories.

Lavoisier made a strong distinction between such cases as salt or sugar dissolving in water and a metal dissolving in an

acid. The latter process he called dissolution. The recovery of the salt or sugar is simple, that of the metal from solution in an acid is difficult. The solution of a metal in an acid is an undoubted chemical process, the solution of a salt in water might as well be regarded as a physical as a chemical process.

Lavoisier also drew attention to the fusibility of salts, and concluded that "caloric" and water would aid one another in dissolving matter, i.e., solubility should increase with rise in temperature. Though true in most cases, certain salts, such as calcium sulphate, exhibit decrease in solubility with increase in temperature.

Richter and Berthollet differed from Lavoisier in regarding solution as caused by chemical affinity. Since the composition of a saturated solution changes with temperature, Berthollet denied the law of constant proportions; the establishment of the atomic theory on an experimental basis negated Berthollet's view. Further, Gay-Lussac (1805) discovered that the volumes of two gases, measured under equal conditions of temperature and pressure, which unite to form a compound, bear a simple relationship to one another. This was followed by the law of Avogadro (1811), according to which equal volumes of different gases, under the same conditions as to temperature and pressure, contain equal numbers of molecules.

#### MATHEMATICAL CHEMISTRY

The kinetic theory of gases was developed on the mathematical side and led to estimates of molecular and atomic dimensions; the atomic theory seemed to have been thoroughly established. Opposition to the theory recurred towards the end of the last century (Wald, Helm), and received some support (Ostwald, le Chatelier); the matter is now of purely historical interest.

The analogy between the Brownian movement (discovered by the English botanist, Robert Brown, in 1827) of small particles, such as pollen grains, and the translatory motion of the molecules of a gas was eventually recognised and the mathematical theory worked out by von Smoluchowski and Einstein. Convincing proof was afforded by the experiments of a number of workers, especially Svedberg and Perrin, and the results were used to calculate the number of molecules,  $N$ , in a gram-mol. of a gas, e.g., in 32 grammes of oxygen. The most reliable results of Svedberg and his pupils is  $N = (6.0 \pm 0.005) \times 10^{23}$ . Fletcher's figure is very close, Perrin's value about 10% higher.

Rutherford, Geiger and Regener counted the number of  $\alpha$  particles emitted by a given quantity of radium in a second, and determined the rate of decay of radium. As, according to Faraday's law, the charge of a gramme of hydrogen ion is 96,550 coulombs, they could determine the charge of an  $\alpha$ -particle, which is double as great as that of a  $\beta$ -particle, the smallest known quantity of electricity, or the atom of electricity. Rutherford in this manner found  $N = 6.2 \times 10^{23}$ . Dewar and Boltwood found independently of each other  $N = 7.1 \times 10^{23}$ . The exceedingly accurate measurements of Millikan gave the electrical atom,  $e$ , equal to  $(4.774 \pm 0.005) \times 10^{-10}$  electrostatic units, corresponding to  $N = (6.062 \pm 0.006) 10^{23}$ .

From Planck's theory of heat,  $N = 6.2 \times 10^{23}$ ; the same number is arrived at from measurements of the charge of droplets condensed from water vapour by means of Röntgen rays.

In 1839 Gay-Lussac pointed to the great analogy between a gas and a dissolved substance. In 1870 Rosenstiehl made the following remarkable statement: "The osmotic force is analogous to the elastic force of vapour."

**Use of Thermodynamics.**—Kirchoff applied thermodynamics (1858) to the vapour pressures of solutions, especially of sulphuric acid. The law of mass action was deduced in 1864 by Guldberg and Waage, which they enunciated in 1867 in its present form:

$C(AB) \cdot C(DE) = K \cdot C(AE) \cdot C(DB)$ ,  
where  $C(AB)$  is the concentration of the salt  $AB$ , etc., and  $K$  is a constant dependent on the temperature (and the nature of the solvent). This formula holds good for a homogeneous equilibrium, i.e., one at which the four salts  $AB$ , etc., are totally dissolved. For a heterogeneous equilibrium, at which some salts, e.g.,

AB, are not totally soluble, one has to introduce for C(AB) the concentration of the saturated solution of AB at the given temperature in the solvent used. Guldberg and Waage carried out a great number of experiments, especially on the equilibrium between the concurrent systems  $K_2CO_3 + BaSO_4$  and  $K_2SO_4 + BaCO_3$ . They also made investigations on the velocity of reactions, especially of the solution of metals in acids. They maintained that the velocities of reaction at a given temperature are proportional to the concentration of the reacting substances, in this case the acid. The last equation therefore says that the quantity of  $AE \times DB$  formed in a certain time is equal to the quantity of  $AB \times DE$  transformed back to AE and DB in the same time.

In 1869 and 1873 Horstmann deduced from thermodynamics the laws of chemical equilibria between gaseous substances. He found his conclusions verified by experiments. The theory of Guldberg and Waage was further simplified when Horstmann showed that his formula (for gases) was applicable.

*Latent Heat.*—From the second law of thermodynamics, Clapeyron had shown that the latent heat of vaporisation of water could be determined from measurements of the pressure of its saturated vapour at different temperatures, and, in 1869, utilised the formula of Clapeyron for calculating the heat of vaporisation of ammonium chloride from the observed vapour pressure. From the known heat of formation of calcium carbonate, Horstmann (1870) calculated dissociation pressures which were verified by comparison with Debray's experimental values. Similar calculations were made with regard to the pressure of water vapour over sodium phosphate dodecahydrate.

Two years later Guldberg took up the question of the evolution of carbon dioxide from calcium carbonate and deduced the famous formula:

$$\frac{d \log p}{dT} = \frac{g}{ART} = \frac{Q}{2T}$$

where  $p$  is the dissociation pressure,  $T$  the absolute temperature,  $R$  the gas constant,  $A$  the inverse value (1.426) of the mechanical equivalent of heat, and  $g$  the heat of dissociation of 1 gramme;  $Q$  is the corresponding value for 1 gramme-molecule when  $R = 2$  (more accurately 1.985).

*Equilibrium.*—In 1885, Van't Hoff showed that if a chemical equilibrium is expressed in the form  $A + B + C + \dots = K (E + F + G + \dots)$ ;  $K$  being the equilibrium constant, Guldberg's equation is applicable if  $K$  is introduced in place of  $p$ .

*Dissociation.*—In 1873 Horstmann continued his theoretical investigations on the question of dissociation, using the experimental figures of Wurtz on hydrobromide of amylene,  $C_6H_{11}Br$ , and those of Wurtz and Cahours on pentachloride of phosphorus,  $PCl_5$ .

*Freezing Points.*—In 1867, 1868 and 1870 Guldberg demonstrated theoretically that the lowering of the freezing point of a solution under that of the solvent as well as the corresponding increase of its boiling point are proportional to each other and to the corresponding lowering of its vapour tension under that of the solvent. He gave the constants which represent the factors of proportionality. He verified his conclusions on the figures of Wüllner and of Rüdorff concerning the behaviour of salt solutions in water.

Willard Gibbs' (1879) celebrated memoir on "Equilibrium of Heterogeneous Substances" received little attention at the time of its publication.

Helmholtz (1882) independently developed part of Gibbs' deductions, more especially with regard to electromotive force.

*Boiling Points.*—Raoult gave (1878 and 1882) important data regarding boiling points, vapour pressures and freezing points of solutions of a great number of substances in different solvents, whereas only aqueous solutions had been used previously, the latter behave a little irregularly. He deduced empirical laws, the simplest of these, viz.,

$$\log e \frac{p-p'}{p} = \frac{n}{N+n}$$

where  $p$  = vapour pressure of pure solvent and  $p'$  = vapour pressure of a solution consisting of  $n$  molecules of solute in  $N$  molecules of solvent, was deduced subsequently by Planck from theoretical considerations. From this formula the corresponding formula for the freezing point and the boiling point may be calculated according to Guldberg's deductions. It is supposed that the solute has no sensible vapour pressure, and that on freezing only the solvent separates out from the solution.

*Electrolytic Dissociation.*—In 1877 Pfeiffer measured the osmotic pressure of a solution of one gramme cane sugar in 99 grammes water at  $6.8^\circ C$ . and he drew Van't Hoff's attention to the measurement of Pfeiffer. Van't Hoff found that if the molecular weight of cane sugar is 342, and if it were possible to vaporise 1 gramme of sugar at  $6.8^\circ$  so that it filled 100 c.cm., it would exert a pressure of 508 mm. mercury according to Avogadro's law. The osmotic pressure is therefore within the errors of observation, and equal to the pressure the same quantity of matter would exert as a gas. This was of practical importance in determining molecular weights. Van't Hoff showed that two solutions of the same osmotic pressure possess common freezing point (or boiling point or vapour pressure), and proved his thesis by Raoult's experimental values. Electromotive forces and chemical equilibria were attacked successfully, the vapour pressure  $p$  in Guldberg's equation being replaced by the equilibrium constant,  $K$ .

It was found that in the case of strong acids, strong bases and salts the molecular weight as determined by lowering of vapour pressures, lowering of freezing point, or rise in boiling point, was always less than the generally accepted value. This necessitated the use of an "isotonic coefficient,"  $i$ , in the case of strong electrolytes. Thus, for instance, potassium chloride in a solution of 0.3% possesses a molecular weight of only 39.2, i.e. 1.9 times less than 74.5. This seemed very improbable.

*Electric Conductivity of Solutions.*—In order to understand this, we must consider the electric conductivity of salt solutions. Faraday found the first and fundamental law of this phenomenon. He observed that the quantity of metal deposited by a galvanic current on an electrode is proportional to the quantity of electricity which has passed through the electrode and also proportional to the equivalent weight of the metal. The first law is very natural; it was already enunciated but not strictly proved by Berzelius. The second law, Faraday's law, says that equivalent quantities of different metals—and the same is true for other substances—are deposited on electrodes after the same quantity of electricity has passed through them.

Kohlrausch found that the molecular conductivity of a salt solution in water, i.e., its specific conductivity divided by its concentration, increases with dilution. The ions of the salt carry the electricity with them according to Faraday in equal quantity for each ion—we suppose, for simplicity, that the ions are univalent. Now, in dilute solutions every ion travels independently of the other ions, and its mobility is dependent only on the viscosity of the solution which is caused by the friction against the solvent, in this case water. Therefore, in highly diluted solutions every ion should contribute just as much as every other ion of the same kind to the transport of electricity—in other words, the conductivity should at a given temperature be strictly proportional to the number of ions, i.e., to the concentration of the salt. Since the conductivity increases at a slower rate than the concentration, the simplest explanation is to suppose that only some of the molecules conduct, the others not taking part. With increasing dilution, the non-conducting become conducting molecules.

Experience shows that the molecular conductivity, i.e., the specific conductivity divided by the molecular concentration, increases asymptotically to a maximum value for infinite dilution, at which all molecules are conducting. If the molecular conductivity at a dilution  $\nu$  is called  $\mu_\nu$  and that at infinite dilution is called  $\mu_\infty$  the fraction of conducting molecules is evidently  $\mu_\nu/\mu_\infty$ . This is of course true only at constant temperature and for rather dilute solutions, the fluidity of which may be regarded as equal to that of pure water. This fraction is called

the coefficient of dissociation, because we must suppose that the non-conducting molecules have their generally accepted molecular weight, just as other non-conductors according to Van't Hoff's law. On the other hand, the conducting molecules, e.g., of KCl, possess their conducting power only because their ions, the kation, in this case K, and the anion, Cl, carry their atomic electrical charges ( $4.774 \times 10^{-10}$  electrostatic units, positive for each ion K and negative for each ion Cl) in opposite directions through the solvent. It is evident that these "migrating" ions move freely until they meet an ion of opposite sign and unite with it, thus forming a non-conducting molecule, the total charge of which is zero, and which therefore does not move along the potential gradient. In other words, we conclude that the conducting molecules are decomposed into their two ions and the degree of dissociation is measured by the fraction.

**Dissociation.**—It is evident that a molecule dissociated into two free ions must exert double as great an influence on the lowering of the freezing point as a non-ionised molecule. If a molecule gives three ions, as for instance  $\text{BaCl}_2$ , its action is three times greater after the dissociation than before it. Generally, if a molecule gives  $n$  ions its influence becomes  $n$  times greater in the dissociated than in the undissociated state. It is easy to see that this circumstance gives a possibility of calculating the degree of dissociation by means of determinations of the freezing point, or of the osmotic pressure of vapour pressure, or even of the boiling point of a solution according to Raoult's laws.

The solid basis of the theory of electrolytic dissociation is the good agreement between the degrees of dissociation calculated for dilute solutions from the electric conductivity and from the freezing point.

**Electromotive Force.**—In 1877 and 1882 Helmholtz gave a thermodynamical theory of the electromotive force of galvanic cells which he confirmed by measurements, especially of concentration elements. In 1888 and 1889 Nernst developed a theory of concentration elements founded on the theories of osmotic pressure and of electrolytic dissociation. It gave the same results as the theory of Helmholtz for the total electromotive force. But Nernst went further. He calculated the three electromotive forces, at the junction between the two electrolytic solutions of different concentration and at the two contact surfaces between metal and electrolyte. In this latter case he expressed the potential difference with aid of his conception of the "solution pressure." Planck gave in 1890 the theoretical formula for the more general phenomena of potential differences at the contact surfaces between any two electrolytic solutions. Negbauer confirmed experimentally the theory of Planck. The oxidation- and reduction-elements were also investigated from this theoretical view point by Bancroft.

**Transport or Migration Numbers of the Ions.**—Hittorf determined the change of composition in different parts of a solution contained in a long glass vessel, through which an electric current of given strength was carried during a measured time. In this manner he could calculate how much the positive and the negative ion each contributed to the conductivity. The corresponding partial conductivities are called the transport numbers of the ions. If their sum is taken as unity, they are called migration numbers.

The molecular conductivity of a solution is equal to the sum of the two transport numbers of the ions, multiplied by the degree of dissociation. These numbers increase rapidly with temperature, owing to the simultaneously diminishing frictional resistance to the motion of the ions. This resistance is regarded as chiefly due to the viscosity of the solvent. In water, the fluidity is nearly exactly proportional to the transport number of the acetate ion in the interval  $0^\circ$  to  $156^\circ$ . The partial conductivities of the different ions approach to that of the acetate ion and to each other with rising temperature between  $0^\circ$  and  $306^\circ$  according to experiments of A. A. Noyes.

**Theory of Diffusion.**—Closely connected with his theory regarding electromotive forces stands Nernst's theoretical calculation of the diffusion coefficients for different electrolytes. Here he

supposed that the dissociation of the electrolytes was complete. His results agree fairly with experimental values found by different observers. The theoretical value is a little higher than the experimental one, which is easily explicable, as the dissociation is not complete and the osmotic pressure has not attained the limiting value.

Nernst's formula indicates that HCl will diffuse more rapidly if a salt is added to its solution. This is easy to understand. If the H ion were alone in the solution, it would at  $18^\circ$  move 4.8 times more rapidly than if the Cl ion were alone in the solution. But electrical forces cause them to move together, whereby the velocity of the diffusion diminishes to a mean value, 2.95. It is easy to show that the diffusion of H (in HCl) increases with addition of sodium ions in good agreement with calculation (Arrhenius, 1892). This is the most direct proof of electrolytic dissociations.

**Additive Properties.**—If we dissolve a substance in water at a given temperature, we find that a certain property, e.g., the specific gravity, increases (or decreases) nearly proportionately to the percentage or concentration of the dissolved substance. For sufficiently dilute solutions the proportionality is exact.

If the dissolved substance is dissociated, the property  $P$  may be expressed as the sum of three terms, the first one the property  $P_w$  of the solvent, mostly water, and the two others proportional to the concentration of the dissociated parts, mostly ions. In other words, the following equation holds:

$$P_{ij} = P_w + K_1 C_i + K_2 C_j$$

If there are only two ions  $I$  and  $J$  the two terms  $K_1 C_i$  and  $K_2 C_j$  suffice.  $K_1$  and  $K_2$  are two constants, characteristic for the ions  $I$  and  $J$ . If we now dissolve another substance, e.g., a salt, which dissociates into the ions  $I$  and  $L$ , we have

$$P_{il} = P_w + K_1 C_i + K_3 C_l$$

consequently;

$$P_{ij} - P_{il} = K_2 C_j - K_3 C_l$$

If we now choose the concentration, e.g., expressed in molarity equal to  $n$

$$P_{ij} - P_{il} = n(K_2 - K_3)$$

In other words, the difference between the properties of two salts with a common ion  $I$  is proportional to the concentration and to the difference between two constants  $K_2$  and  $K_3$  characteristic for the two ions  $J$  and  $L$ ; they may be accompanied by any ion  $I$  of the opposite electric charge. This is the law of additive properties, which is only valid for totally dissociated salts, i.e., at extreme dilution. But it is found that also for higher concentrations this law is often valid. This depends upon the circumstance that in many cases the effect of the undissociated part is very nearly equal to the sum of the effects of the ions contained in it. This peculiarity is often explained so that the salt is completely dissociated. But in some cases, e.g., for the lowering of the freezing point, it is found (by Raoult) that the property is not additive, which depends upon an incomplete dissociation.

#### THERMOCHEMISTRY

During chemical changes heat is usually evolved or absorbed, the amount depending generally on the temperature at which the change takes place. Many measurements were made by Berthelot and Julius Thomsen in the latter part of the 19th century.

Before the introduction of the calorimetric bomb (constant volume method) determinations of the heat evolved or absorbed were usually carried out at constant pressure. Since change in volume generally occurs, the results obtained need correction in order to obtain the theoretically more important value, the heat of reaction at constant volume. For if a reaction takes place at constant pressure  $p$  and the volume  $v$  at the end of the reaction is less than  $v_0$  the initial volume of the reacting substances, the amount of work  $p(v - v_0)$  done by the system

on the surroundings has a negative value, *i.e.*, this amount of work has been done on the system and the heat of reaction is correspondingly greater than if the reaction had taken place at constant volume.

Frequently, the heat of a reaction *A* is incapable of direct measurement. Usually it is possible to carry out two (or more) partial reactions *B* and *C* whose algebraic sum is equal to *A*. For the heat changes  $U_A$ ,  $U_B$ ,  $U_C$  we have the equation

$$U_A = U_B + U_C.$$

so that two of the quantities being known from experiment we obtain the third by addition.

Berthelot and Thomsen believed that the direction of a reaction depends on *U* being a positive magnitude, *i.e.*, heat being evolved. Reactions in which heat is evolved are called exothermic, those in which it is absorbed, endothermic. Berthelot tried to explain the occurrence of endothermic processes by maintaining that foreign (not caloric), *e.g.*, electrical energies, interfered in the process. Now we know that the free energy, usually denoted by *A*, is the determining quantity, and thereby the values of *U* have lost a great part of their importance. It is to be observed that at absolute zero  $U=A$ , and that at low temperatures the difference  $U-A$  is rather small compared with *U* in most cases, therefore the mistake of the thermochemists is explicable.

The values of *U* and *A* may easily be calculated if we know how *U* changes with temperature. According to a theoretical formula of Debye the specific heat is proportional to the third power of the absolute temperature in the neighbourhood of absolute zero. With the knowledge of the specific heats of the reacting substances at higher temperatures it is possible to find the value of *U* at any temperature with sufficient approximation, if this value is known at ordinary temperature. At  $T=0$ ,  $U=A$ . As according to the second law of thermodynamics,  $TdA = (A-U)dT$ , it is possible to find *A* at any temperature, when *U* and  $dA-dT$  are known, as Nernst describes in his treatise on "the new heat-theorem." The free energy *A* corresponds to the potential energy in mechanics, and therefore any chemical reaction will proceed in such a direction that *A* decreases. In certain cases *A* can be measured directly, as with galvanic cells.

**Chemical Equilibria.**—The simplest case of an equilibrium is that between a liquid and its vapour; discussed above. The same formula is valid for the solubility of a substance in a solvent, and also for the equilibrium-constant, characteristic of a chemical reaction. The simplest chemical reaction is that of the undissociated part of an electrolyte with its ions. This equilibrium has been investigated by Ostwald for weak acids and by Bredig for weak bases, and it has been found valid (Ostwald's law). By means of the change of the equilibrium constant of weak acids Arrhenius calculated their heat of dissociation and from this their heat of neutralisation in good accordance with thermochemical observations. The equilibrium constant of dissociation in all cases investigated at not too low temperatures diminishes with increasing temperature, whereby the heat of dissociation is found to be negative at higher temperatures. Therefore some weak acids possess a lower conductivity at higher than at lower temperatures, which was previously regarded as impossible. The calculations agree very well with the observations.

**The Phase Rule.**—For heterogeneous equilibria, Gibbs has given his important phase rule. We may at first regard the simple case of water. Water occurs in three different modifications, as ice, water and vapour. For each of these is valid an equation of condition  $f(p,t,c) = 0$ , where *p* and *t* represent the obtaining pressure and temperature and *c* is the concentration of the substance in the ice phase, liquid phase and vapour phase. If the three phases co-exist in a vessel, we have three equations for determining the three variables. From the tables of vapour pressure at different temperatures we find  $p=4.57$  mm. Hg,  $t=0.0076^\circ\text{C}$ . The three concentrations are proportional to the densities. Here we have only to do with one substance. The number of phases is three. If we had put a sufficient quantity

of a soluble salt, *e.g.*, sodium chloride, in the water, two solid phases—one of ice, another of salt crystals, one fluid—salt solution, and one gaseous—water vapour would have been present. These can only co-exist at the eutectic point,  $-21.3^\circ$ . In general, if we have *n* substances they may give  $n+2$  phases at the "point of transition." If we take away one phase, *e.g.*, the solid in the first example, we have only two phases, vapour and fluid, above the transition point. Then we may fix one of the variables *p* or *t*, but then the other becomes determined, *e.g.*, *p* as a function of temperature. If also another phase, *e.g.*, the gaseous one, disappears, we may choose any pressure and temperature, but if these are fixed, we obtain also a fixed concentration, which in this case may be expressed in gramme water per cubic centimetre. The phase rule owes much to Roozeboom and Schreinemakers, and Van't Hoff has applied it in his remarkable investigations on "oceanic deposits of salts."

An interesting equilibrium is that which occurs when an acid is added to a solution of a salt of another acid. In this case a certain quantity of the corresponding salt of the first acid is formed. Julius Thomsen and Ostwald determined this decomposition by thermal and optical measurements. Arrhenius found very good agreement of these values with those calculated from dissociation constants.

**Adsorption Phenomena.**—If we have a substance, *e.g.*, acetic acid, dissolved in water containing charcoal particles in suspension, we find that a great deal of the acid is "adsorbed" by the particles so that after some time equilibrium is attained, at which point, according to Freundlich,

$$y = KC^n,$$

where *y* is the adsorbed quantity per gramme of charcoal, *K* is a constant dependent on the origin and history of the charcoal and the temperature, *C* is the concentration of the acid remaining in the aqueous solution, and *n* a constant number. This equation has been verified in a great number of cases, though the theoretical deduction is lacking. At high values of *C*, *n* diminishes with increasing *C*.

The adsorption phenomena play a very great rôle in colloidal chemistry, and therefore also in biochemistry. (See COLLOIDS and BIOCHEMISTRY.)

Amphoteric electrolytes which have both basic and acid character play an important rôle in biochemistry; their equilibria have been investigated by many biochemists, especially by Jacques Loeb.

**Velocity of Reactions.**—The rate of change of a chemical process is proportional to the concentration of the catalyst (*q.v.*) and that of the substrate. Sometimes the quantity of the catalyst changes also during the chemical change. In this case the change of its concentration must be taken into consideration. Of this kind are the so-called autocatalytic processes. The agreement of theory with experiment is satisfactory. The effect of the catalyst in most cases  $H$  or  $OH'$  ions is affected by the presence of neutral salts, the so-called salt-action. In most cases their action accelerates the velocity; in some cases, *e.g.*, saponification of esters, the velocity diminishes when salts (of the type  $KCl$ ) are present.

Arrhenius found that the same equation is valid for the increase of the velocity of reaction with temperature as that for the corresponding change of the constant of equilibrium. This equation has proved to be generally valid. He therefore supposed that only a very small part of the substrate reacts chemically which is in chemical equilibrium with the chief, very nearly total, quantity of the substrate. The "active" part of the substrate may be an allotropic form of the chief part, or it may consist of the molecules which have a very great molecular motion (Marcellin). Trautz, McC. Lewis and Perrin independently of each other expressed the idea that the radiation of heat provokes the formation of the active substrate, and that a special radiation, in most cases infra-red and different in different cases, activates the molecules. It is difficult to give experimental proof of this theory.

The "heat of activation" *Q* in the formula is very different

in different cases. For the reactions investigated, saponifications of ethyl acetate and inversion of cane sugar by acids,  $Q$  has the values 5,579 and 12,800, which are of the same order of magnitude as that of  $Q$  for common chemical processes. For biochemical processes we find very different values, from  $Q=3,150$  for the precipitation of egg-white, and  $Q=5,000$  for the inversion of cane sugar by means of invertase, up to  $Q=81,000$  for the spontaneous destruction of tetanolyisin and  $Q=99,200$  for that of a haemolysin from goat-blood.

The spontaneous decomposition of the radioactive substances does not change within the very widest limits of temperature. The same is the case for some photo-chemical processes such as the common photographic process with silver bromide and gelatine, or the reaction of oxalic acid with ferric chloride. In other cases the temperature has a comparatively small influence ( $Q$  is sometimes about 2,000) on photochemical processes.

**Activity.**—The determination of dissociation constants by different methods, e.g. electric conductivity, electromotive force of concentration cells, lowering of freezing point, etc., only gives concordant results in the case of dilute solutions. For concentrated solutions disagreement results from the circumstance that the conductivity depends upon the molar concentration, whereas the thermodynamic phenomena are connected with the numerical concentration. But even in rather dilute solutions, below 0.1 normal, for which the two kinds of concentration are very nearly proportional, very great discrepancies are observed. This depends on the corrections which should be applied in different cases. Milner showed that a correction ought to be introduced for the thermodynamic quantities, especially the value of the molecular lowering of the freezing point. Debye and Hückel found that another correction should be applied to the determinations of molecular conductivity. These two corrections are due to the influence exerted by the electrical charges of the ions. Other corrections are due to the viscosity, which has a great influence on the conductivity but probably none or only a very small one on the freezing point. In great dilutions this correction vanishes. But this is not the case with that due to the hydration of the ions, which has an opposite influence on the conductivity to that on the freezing point. Even the change of the dielectric constant may have some influence. These different corrections are still only imperfectly investigated.

In order to escape all these difficulties, many authors as Milner, Debye, and Hückel, accepted an idea of Sutherland, that the strong electrolytes are completely dissociated, or they may practically be regarded as completely dissociated (Bjerrum). It is also maintained that even crystals are completely dissociated, because their Röntgen-spectra are caused by atoms and not by molecules, that therefore we must suppose that also the most concentrated solutions of strong electrolytes are completely dissociated. It is difficult to understand this, for ions are free to move under the influence of electrical forces, and that is very rarely the case with the atoms of a crystal. It is true that such a migration is found for sodium atoms in quartz crystals, but they must be regarded as being in solid solutions together with  $\text{SiO}'_3$ -ions in the crystal. Glasses are also electrolytes, but are regarded as extremely viscous fluids.

The change of the molecular freezing point and of other connected properties with concentration is explained as depending on a property called activity, which is empirically determined, but so that the thermodynamical laws shall be valid. The investigations regarding activity have increased our knowledge, but a theoretical explanation of the physical causes for the complicated change of the activity with concentration has not been given.

**PHYSICAL TRAINING.**—The history of physical training since 1910 has been marked by (1) a notable improvement in the whole basis of the training itself, (2) a growing recognition of the value of such training during the formative years of childhood, and (3) the growth of administrative measures directed toward the establishment of a uniform system of training in all the schools which form part of the national system of education.

## I. IN GREAT BRITAIN

Until 1902, physical training was permissive in the elementary schools; in that year it was established as an integral part of the curriculum, and the Board of Education issued a model course for the upper departments of the schools. Under successive revisions the model course, which originally consisted largely of military drill, has developed into the present Syllabus of Physical Training, based on the Swedish system and providing for the needs of all children between the ages of 5 and 14. Faith in the sufficiency of mechanical drills has been succeeded by a broad conception of physical education as a many-sided and vital process, directed to securing the careful and well-balanced cultivation of the physical powers of each individual child, and to the formation of habits of self-discipline by learning to control the body and to work in harmonious concert with others. Physical education as now understood includes systematic and graded exercises chosen for their physiological and corrective results, folk-dancing, swimming, organised games and sports, in fact all those things which make for physical well-being, implant a love of healthy outdoor pursuits, and contribute to the making of useful citizens.

In 1909, the medical department of the Board of Education was made responsible for the inspection of physical training in all state-aided schools and institutions and for the general supervision of the arrangements made for such training by the local education authorities. In all the elementary training colleges physical training as a professional subject was made compulsory, and encouragement was given for the formation of courses for the teachers already in the schools. A special grant was established in 1917 for the purpose of encouraging local education authorities to employ expert organisers of physical training, who should assist the teachers by advice, demonstration and training to make the most of their opportunities. The results obtained have abundantly justified the policy of the grant, and have shown that the organiser is an essential factor in a scheme of training under which the class teacher is responsible for the instruction of his own class. The physical training in the elementary schools has thus been directed into the right paths and the efficiency of the teaching steadily improved.

The varied problems connected with the physical training of adolescent girls and boys are not capable of solution on the basis of a common syllabus for secondary schools. Reliance therefore has to be placed on the trained teacher who can formulate and carry out his own schemes. Girls' secondary schools can generally obtain the services of an expert teacher trained at one of the several physical training colleges for women. For this reason the physical training at the girls' schools, at least in the better ones, has for some time been conducted on the right lines.

**Training in Secondary Schools.**—Much less progress has been made with the boys' secondary schools, due partly to the lack of properly trained men teachers and partly to the fact that the need for systematic training has not been so fully recognised. The tendency has been to regard games as sufficient for the boys' physical development. It must, however, be admitted that the physical training of which these schools have had experience has not inspired general confidence in the efficacy of this form of instruction. Recent experiments indicate that a specialist training in physical education is unlikely to attract men of the right type in sufficient numbers to make the institution of a prolonged course of training an economically sound proposition. A solution may be found in encouraging the ordinary form masters to take part in the work after undergoing a short course of training, and in providing some instruction for students in secondary training colleges.

Secondary schools generally have facilities for physical training which the elementary schools do not possess; they have their own playing fields and usually some form of indoor accommodation, often a gymnasium, the classes are smaller and suitable clothing is worn. But in many of the secondary schools the growing pressure of whose academic work is often allowed to crowd physical training out of the time-table of the older pupils, the advantage of systematic physical training throughout the whole of school life needs to be more fully recognised. (See EDUCATION: Literature.) (F. H. G.)

## II. IN THE UNITED STATES

Physical education advanced with giant strides in the United States during the years 1910-26. The World War had a powerful influence in centring attention on this subject, because one out of every three who were examined for service was rejected on account of disability. Before 1915, only three states had laws requiring the teaching of physical education in the public schools. During the period of the World War and the three years following, 25 states passed Acts compelling the teaching of physical education, and between 1921 and 1925 six other states passed similar laws, bringing the total to 34.

Most state laws provide for the organisation and supervision of courses in physical education for both sexes in the elementary, secondary and normal schools. Many states have made provision for training teachers in this subject in the normal schools, the courses for which must be passed satisfactorily before candidates are given their licence to teach. The professional training of teachers has contributed greatly to the advancement of physical education. There were in 1925 more than 40 schools, including normal schools, colleges, universities and private schools which graduate well-trained teachers, and the number is rapidly increasing. About 95% of the preparatory schools, colleges and universities have departments of physical training. Several states have a state director of physical education with assistants to supervise the work. It also has become the practice in large cities to have directors. The time requirements for exercise for the pupils average from 15 to 30 min. daily. It is estimated that the total cost of physical education in the public schools of the United States was in 1925 more than \$15,000,000.

*Systems of Training.*—The German and the Swedish systems made definite contributions to the cause of physical education, but their formal work found their strongest opponent in the British system of playing games, which gradually has become the dominating principle of physical education in the United States. Marching, dancing, free-hand exercises and calisthenics with dumbbells or wands, usually form a part of the formal drills, but emphasis is laid upon the exercises in which play is the central theme. No nation in the world has so many outside agencies organised to promote the spirit of play either as a means of physical education or in conjunction with its main purpose.

Foremost among these is the Playground and Recreation Assn. of America, which is aggressive in arousing public interest in favour of play spaces with instructors, especially for the children. As a result of the momentum given, in part by this association, more than \$20,000,000 are now expended annually in the United States for public recreation. Many thousand paid and voluntary workers give instruction in organised play in over 8,000 playgrounds and gymnasiums. Several other national organisations, working independently, practically all being constituent members of the National Amateur Athletic Federation, are promoting and administering programmes of physical education, some of them of a high order. Among these should be mentioned the Y.M.C.A., the Y.W.C.A., American Turner Bund, American Legion, Bohemian Sokol, The National Assn. of State High Schools, Boys' Club Federation, Catholic Boys' Brigade, Boy Scouts of America, Girl Scouts, Camp Fire Girls, Jewish Welfare Board, Order of DeMolay, The National Collegiate Athletic Assn., the Amateur Athletic Union and the Knights of Columbus. Other organisations not now nationally organised, such as Municipal recreation depts., athletic clubs, industrial companies, settlement houses, Churches and Sunday schools, civic and fraternal organisations, etc., also are doing valuable work in physical education. It is estimated that more than 10,000,000 boys of elementary and high school age receive physical training from the above and other organisations mainly in athletic games. (A. A. Str.)

**PHYSICS.**—While recognising the tendency of each generation to consider itself important and its contributions to progress unique, the historian of the future will probably estimate the 30 years ending with 1925 as the most extraordinary in the history of the world up to the present in the number and the fundamental character of the discoveries in physics to which they have given birth, and in the changes brought about by these discoveries in man's conceptions as to the nature of the physical world in which he lives.

There has been no period at all comparable with this unless it be the period about 300 years ago, which saw the development of Galilean and Newtonian mechanics. This was indeed of incalculable importance for the destinies of the race. The conceptions then introduced are not only the basis of modern *material* civilisation, but they were the cause of a very complete change in man's whole intellectual and spiritual outlook—in his philosophy, his religion and his morals. But the discoveries in physics of the past 30 years justify the expectation, at least, of as great if not greater consequences—consequences, too, which are already beginning to be realised.

To appreciate how stupendous a change these discoveries have already wrought in human thought, it is only necessary to reflect that of the six basic principles which at the end of the 19th century acted as the police officers to keep the physical world running in orderly fashion, namely,

1. The principle of the conservation of the chemical elements,
2. The principle of the conservation of mass,
3. The principle of the conservation of energy,
4. The principle of the conservation of momentum,
5. The principle underlying Maxwell's Electrodynamics,
6. The principle of entropy or the second law of thermodynamics,

there is not one, the *universal* validity of which has not been questioned recently by competent physicists, while most of them have been definitely proved to be subject to exception.

The principle of the conservation of the chemical elements went with the discovery of radioactivity. The principle of the conservation of mass vanished with the experimental discovery of the increase in the mass of the electron with speed as the velocity of light is approached. The principle of the conservation of energy suffered a change in aspect when both experimental and theoretical evidence came forward that energy and mass are related by the Einstein equation  $MC^2 = E$ , for in that equation the ideas of energy and of mass become completely scrambled. The principle of the conservation of momentum is denied *universality* by the quantum theory. The Maxwell equations are violated in atomic mechanics. The principle of entropy was admitted to have exceptions as soon as entropy was interpreted in terms of "probability."

Further the speed with which new discoveries and new points of view are coming into modern physics shows as yet no abatement. Fifteen years ago it was thought that the revolution had pretty well spent its force, that the main group of new ideas had already been introduced. But a listing of the most outstanding discoveries of the past 30 years shows that the great majority of them belong exclusively to the period here in review—namely, the last 15 years—and all of them belong at least in part to this period. The immensity of the progress made within it will be best appreciated through a rapid review of this whole list and brief comments upon the origin and the particular significance of each discovery.

1. *The Discovery of the Electron.*—This was a very gradual process covering about 150 years and participated in by many workers. Franklin, Faraday, Weber, Helmholtz, Stoney, Lorentz, Zeeman, J. J. Thomson, Lenard, Townsend, Wilson and others,<sup>1</sup> but the actual isolation and the exact measurement of the electron occupied the first seven years of the period in review,<sup>2</sup> 1910-25.

2. *The Discovery of X-rays.*—This falls clearly outside the present period but practically the whole of the *quantitative working out* of the properties of X-rays and the great discovery in 1912 of their wave nature<sup>3</sup> lies wholly within it.

3. *The Discovery of Quantum Mechanics.*—This began at about the year 1900 with the work of Planck, but the last 15 years have contributed enormously to it, as will appear as the enumeration of discoveries proceeds.

4. *The Discovery of the Principle of Relativity.*—Though the special principle dates from about 1905 and therefore lies within the first half of the last 30-year period, the formulation by Einstein of the general principle belongs wholly to the period in review. Its birthday was in 1915 and its most precise and significant experimental verification through the measurement of the bending of starlight in going past the rim of the sun, the discovery of the enormous spectral shift of lines coming from the companion of Sirius,<sup>4</sup> and the beautifully consistent measurements of the displacements of solar spectral lines,<sup>5</sup> has all been the work of the past few years. It is too early to estimate the significance of D. C. Miller's very recent observations on ether-drift.

5. *The Discovery of Radioactivity.*—This belongs indeed wholly to the first half of the 30-year period, but the definite proof that lead is a product of the radioactive disintegration of both uranium and thorium, and the application of this fact to the fixing of the minimum age of certain uraninites from the Black Hills in South Dakota as 1,677,000 years,<sup>6</sup> to take but a single concrete case, is very new and marks an important advance in the process of elaborating a very much more definite geologic time scale than has heretofore been available.

6. *The Discovery of the Nuclear Atom,* through the experiments on x-ray scattering begun about 1912 and carried on for 10 years, mostly at Manchester and at Cambridge, England,<sup>7</sup> falls wholly within the last 15-year period and has been epoch-making in its consequences.

7. *The Discovery of Crystal Structures,* through the aid of X-ray spectroscopy<sup>8</sup> dates from only 1913. It has completely revolutionised crystallography and opened up a new world of definite knowledge about molecular and atomic arrangements in solids.

8. *The Discovery of Atomic Numbers* (1913-24) and the definite fixing of the total number of possible elements between hydrogen and uranium as 92,<sup>9</sup> both being included, is perhaps the most beautiful and the most simplifying discovery ever made. Nature never came so near surrendering herself to her lover without reserve and revealing herself in beautiful and simple grandeur as when Moseley found that all the elements fitted into a single arithmetical progression—a progression, too, which could mean nothing except that the positive charge on the nucleus of each atom moved up by unit steps from 1 to 92 in going from hydrogen to uranium—a progression which at once robbed atomic weights of their long-usurped right to act as arbiters of the chemical destinies of atoms, and restored this place to its legitimate possessor, the electrical charge of the nucleus. Some day a poet will arise who will make an epic for the ages out of young Moseley's discovery. The X-ray spectroscopists<sup>10</sup> and those who have recently extended the X-ray laws into the field of optics,<sup>11</sup> have contributed to the establishment of the complete generality of the Moseley progression, but they have merely finished the structure which he designed.

9. *The Discovery that the Energy Communicated to Electrons by Ether Waves is Proportional to the Frequency of the Absorbed Waves.*—This was vaguely suggested by Planck in 1900, more specifically by Einstein in 1905, but the experimental proof of its correctness is perhaps the most momentous achievement of modern physics, and it has all come about since 1912. The achievement is momentous not merely because the equation  $\frac{1}{2}mv^2 = h\nu - P$  ranks with the equations of Maxwell in its consequences, but because the relation itself is new, undreamed of in 1895, and altogether revolutionary, demanding a return to some elements of the corpuscular theory of ether waves. It was proved first very exactly in photoelectric experiments with light waves,<sup>12</sup> then during and after the War with X-rays,<sup>13</sup> and then with  $\gamma$ -rays.<sup>14</sup> Most of the preceding discoveries were wonderful additions to knowledge, explorations in heretofore unknown fields but not subversive of established conceptions. This one, however, wrought havoc with existing theories and demanded a

new formulation of ideas about the relations of ether physics and matter physics. Its significance for the future can scarcely be overestimated.

10. *The Discovery of the Meaning of Spectral Lines.*—Bohr<sup>14</sup> in setting up his theory of atomic structure merely generalised the preceding discovery. With unusual insight into the method of constructive science, he incorporated all the past and merely superposed upon celestial mechanics the assumption, almost inevitable (if Einstein's equation is correct) that when an ether wave is emitted as well as when it is being absorbed the foregoing relation between energy and frequency still holds, *i.e.*, that the emitted wave frequency is given by  $E_2 - E_1 = h\nu$ , the  $E_2$  and  $E_1$  being the electronic energy before and after emission. Combining this with the experimentally established Ritz-Balmer equation, he brought out sharply the unitary or atomic character of angular momentum, clearly one of the two or three most fundamental discoveries of all time, for it will presumably always be the basis of all atomic mechanics. It had been dimly glimpsed before in the work of Planck and Einstein, definitely stated by Nicholson and Ehrenfest, but from Bohr's time on Quantum theory took on a definiteness, almost a visualisability before unknown.

11. *The Discovery of Isotopes.*—This discovery did not begin to be made until 1913, when chemists and physicists approached it from two different angles; first, the chemistry of the radioactive elements and second, positive ray analysis.<sup>15</sup> It was completed only after 10 years of work by physicists in analysing by positive ray methods 46 of the first 55 elements of the periodic table. Its significance lies in the four following facts: first, that it has resurrected completely the discredited and amazingly simple Prout hypothesis that the masses of all atoms are exact multiples of the mass of a primordial atom; second, that it has enabled us to count with certainty the exact number of positive and negative electrons inside every nucleus—positives being equal in number to the atomic weight, negatives to the atomic weight minus the atomic number; third, that the failure of hydrogen to fit exactly into the above scheme constitutes excellent evidence for the Einstein conclusion as to the interconvertibility of mass and energy; and fourth, that the difference in stability (decay-time) of radioactive isotopes suggests new possibilities in the reading of the structure of the nucleus, *i.e.*, it gives us new eyes for peering inside the tiniest organism yet found—the nucleus of the atom.

12. *The Discovery of "The Excited Atom."*—The purely theoretical reflections in 1921 of two mere youths in Denmark, Klein and Rosseland, resulting in the proof that if atoms can be thrown by impact, as experiment shows that they can, into a quantum state of higher energy than the normal—appropriately called an excited state—then unless the second law of thermodynamics is to be violated there must be a heretofore unrecognised mechanism by which an excited atom can return to its normal state without radiating at all, but rather by throwing back all the potential energy of its excited condition through a so-called "collision of the second kind" into an electron or an atom projected from the collision with a kinetic energy that may be 100 times the average energy of molecular agitation. This is a very recent discovery of the first magnitude and of possibly immeasurable significance. It has already made it possible through the work of the experimental physicist<sup>16</sup> to see a collision-mechanism by which a negligible number of mercury atoms can absorb ether-wave radiations and transfer that energy to the act of exciting thallium atoms to radiate their characteristic frequencies. It for the first time reveals a definite mechanism, sought in vain by the best thinkers of the 19th century, by which the energy of ether waves may be absorbed by matter and transformed into heat. It takes in one case, at least, the mystery out of the words "catalytic agent." It suggests why very minute quantities of vitamins, etc., may be the intermediaries through which very vital processes are brought about. It makes the future bright with promise for the better understanding of explosive processes. Indeed the properties of excited atoms may possibly be the foundations of a new era in both industrial and biological science.

13. *The Discovery of the Artificial Disintegrability of Atoms.*—This was glimpsed about 1912 through the appearance of hydrogen lines where hydrogen unless artificially produced from other elements should not have been present, and new claims of spectroscopic evidence of a similar sort are now being advanced, but the unambiguous proof is contained in Rutherford's<sup>17</sup> direct experiments showing that hydrogen atoms can be knocked out of other atoms by alpha-ray bombardment. The method shares with that which will introduce new resolution into the study of the masses of isotopes, the promise for the future reading of the conditions of the electrons within the nucleus.

14. *The Discovery of Relativity Inside the Atom.*—It was as late as 1917 before Sommerfeld<sup>18</sup> began his wonderful work on the interpretation of the fine structure of spectral lines—work which began for the first time to reveal the correct principles underlying quantisation, finally so penetratingly formulated by Epstein. Seldom in the history of physics have purely theoretical formulae had such amazing successes in the field of precise prediction as have Sommerfeld's relativity-doublet formulae and Epstein's extension of the same sort of orbit considerations to the prediction of the number and character of the multiplicity of lines found in the Stark effect. The whole interpretation of spectroscopic line structure through changes in so-called azimuthal and inner quantum numbers is one of the great achievements of all time resulting from the interplay between penetrating theoretical analyses and skilful and refined experimental technique.

15. *The Discovery of New Experimental Techniques for Seeing Invisible Ether Waves.*—Such long-wave technique<sup>19</sup> has completely bridged within the past two years the gap between artificial electromagnetic waves and heat waves, and in the short-wave region hot-spark vacuum spectrometry<sup>20</sup> and beta-ray methods of analysis have practically filled in completely the gap between the optical and the X-ray fields, while far above even the gamma rays of radium a new group of rays of well-nigh infinitely high frequency has been found (see below). This continuous passage of frequencies from a thousand billion billion per second, over into the zero frequency, i.e., over into static electrical fields, all these waves possessing identical characteristics as to speed of propagation, as to polarisation and as to relations of electric and magnetic vectors, demands one and the same sort of transmitting mechanism or medium to take care of them all, by whatever name it may be called, whether a "world-ether" or "space," this last term meaning no longer emptiness, but emptiness endowed with definite properties, if such an Hibernicism suits one's taste.

16. *The Discovery of New Properties in Conduction Electrons.*—The direct measurement<sup>22</sup> of the mass of conduction electrons, the discovery of a general increase in conductivity with the application of enormous pressures,<sup>23</sup> of superconductivities<sup>24</sup> and the very recent proof that, when intense electric fields pull conduction electrons out of metals, the energy of thermal agitation assists not at all at ordinary temperatures but does assist at very high temperatures,<sup>25</sup> all these recent discoveries, especially the last, begin to clear up the contradictions in the electron theory of metallic conduction, and to enable the quantum theory of specific heats to be applied in a new and illuminating way to the condition of the electrons in metals. The new results are full of promise for the better understanding in the near future of the moot subject of metallic conduction.

17. *The Discovery of Quantum Jumps Inside the Nucleus.*—The very recent proof<sup>26</sup> that gamma radiations obey the same quantum jump laws obeyed by X-rays and light rays and the still more recent proof that the initial act in a radioactive change is the ejection of an alpha or beta ray—possibly by virtue of the actual loss of mass of the nucleus through electronic settling and the transformation of this mass into the energy of the ray, following the Einstein relation governing the interconvertibility of mass and energy—this is a discovery of the first importance for the future understanding of one of the most fundamental processes in nature, namely the growth and transmutation of the elements.

18. *The Discovery that the Law of the Conservation of Momentum is Applicable to the Encounter Between a Light Quantum and a Free Electron.*—This very recent and very amazing discovery<sup>27</sup> seems to put the final nail into the Einstein conception of radiant energy travelling through space in the form of vibratory light darts of some sort, but at the same time it emphasises the apparent impossibility of the physicist finding in his present stage of development any one consistent and universally applicable scheme of interpretation. It is a discovery of the very first magnitude, one of whose chief values may be to keep the physicist modest and undogmatic, still willing, unlike some scientists and many philosophers, not to take himself too seriously and to recognise that he does not yet know much about ultimate realities.

19. *The Discovery of the Summation of two Quantum Jumps Into a Single Monochromatic Ether Wave.*—The very recent proof brought forth first by the properties of band spectra<sup>28</sup> and second by the discovery of two electron jumps through study of pp groups in line spectra,<sup>29</sup> that an atom can integrate the combined energy of two distinct and simultaneous quantum jumps into a single emitted monochromatic wave, is of fundamental importance, because of the new light which it throws upon the nature of the act in which a ray of light is born and projected on its way through space. The discovery of two electron jumps uniting into a single monochromatic ether wave seems to preclude the possibility that there is any vibrating mechanism in the atom executing vibrations synchronously with the period of the emitted monochromatic wave. That the atom has this power of transforming, in some as yet mysterious way, the energy of every atomic shudder into a monochromatic ether wave is amazing. Whether we shall ever be able to visualise the process more definitely than we can now no one knows.

20. *The Discovery of the Failure of the Relativity Explanation of all Relativity-doublets.*—The impasse pointed out within a year<sup>30</sup> between the heretofore recognised causes of doublets in optics and in X-rays, an impasse which necessitated the finding of a new cause which would yield exactly the same formula as the relativity cause—a really terrible necessity in view of the extraordinary quantitative success of the purely theoretical formula following from the mere postulation of the change of the mass of the electron with speed—this impasse has apparently just been resolved within two months by two young Dutchmen, Oulenbech and Goudsmit, who find, *mirabile dictu*, that the assumption that every electron in the universe spins with one unit of angular momentum either right-handedly or left-handedly yields a formula of exactly the same form as does the relativity cause. This assumption not only saves the relativity explanation but, combined with it, furnishes a much better correlation of all present spectroscopic facts than we have heretofore had. It represents probably a fundamental advance in our understanding of the nature of the most nearly ultimate thing with which physics deals, namely, the electron. The physics of the future bids fair to hear much of the spinning electron.

(21) *The Discovery of Cosmic Rays.*<sup>31</sup>—That something very fundamental is going on all through space, that nuclear transformations each of enormous energy value corresponding to the fall of an electron through as much as 30,000,000 volts, are actually taking place in all directions about us in the outer stretches of the universe and that the signals of these cosmic changes can be detected here has just been proved. It is a discovery most stimulating to the imagination. Call it the music of the spheres if you wish! Anyway man can hear it now and may sometime know more about it.

Of these 21 fundamental discoveries, at least 16 fall wholly within the past 15-year period and all of them have belonged in no small degree to it. Physics as yet seems to show no signs of approaching senility. What the future has in store, no man knows but at present there seems to be well-nigh limitless possibilities ahead for applications even if the pace of discovery should sometime slacken.

mined during short periods of exercise (*i.e.*, both during and following it), the interesting fact has come to light that respiratory quotient equals about 1, which indicates that carbohydrate must be the source of the energy of contraction in the intact animal, just as with isolated muscle. When the exercise is more prolonged the quotient falls below unity, since  $O_2$  has to be retained in order to convert into carbohydrate such substances as fat, which contain relatively less oxygen. This process probably occurs in the liver.<sup>1</sup>

*The Capillary Circulation.*—Since they are composed of thin flat endothelial cells placed side by side, the capillaries have been considered incapable of dilating or contracting independently of changes in the pressure of the blood flowing in them, brought about by variations in the calibre of the minute arterioles. The first to observe independent alterations in the calibre of the capillaries was Stricker (1865) and this was confirmed by Roy and Graham Brown (1879). Convincing evidence was furnished by Dale and Richards, who showed that the capillaries dilate while the arterioles constrict during the depressor action of histamin (B-imin-azoyl-ethylamine), whereas the arterioles alone dilate with acetyl choline. When the rate of outflow was measured in a perfused preparation of the mesenteric blood-vessels, these observers found that acetyl choline always caused dilatation, whereas histamin caused constriction, although both lowered the arterial blood pressure. They also observed that a small dose of histamin, 0.01 mg., caused a flushing of the denervated paw, while acetyl choline had no effect, indicating that the former drug had specifically dilated the capillaries. It was later possible to explain the condition of *shock* following larger doses of histamin as due to extensive dilatation of the capillaries, on account of which the blood stagnates in them.

While the results of these researches made it necessary to postulate alterations in the calibre of the capillaries that are independent of changes in that of the arterioles, they did not furnish direct evidence that this occurs. Krogh examined microscopically the superficial capillaries of the muscles in frogs and mammals, using strong reflected light as a source of illumination. In resting muscles the capillaries are relatively few in number, and so narrow that the red corpuscles can pass along them but slowly and, often, only after marked distortion in shape. After activity, on the other hand, many more capillaries become visible, and the blood flows rapidly through them. As the circulation returns to the resting state, the capillaries again become narrower and many disappear from view; but even in a group derived from the same arteriole all do not behave alike, indicating that the degree of contractility varies. After the congestion caused by the irritation of pinning out the tongue of the frog subsides, many of the capillaries disappear from view. Krogh observed that scratching the surface of the tongue along the course of a small vein might cause a capillary, previously invisible, to become opened up so that corpuscles moved into it. If now the mechanical stimulus was applied in a line just in front of the end of this branch, the dilatation gradually extended, until at last a visible capillary had become formed of sufficient length to join with an arteriole, when the previously stagnant column of blood corpuscles immediately changed into a quickly flowing stream from arteriole to venule. This contractility of the capillaries is believed to depend on the presence of cells (Rouget cells) with numerous protoplasmic branches which encircle the endothelium of the capillary walls.

The tone of the capillaries is controlled partly by hormones and partly by nerves. Krogh found that marked local dilatation of the capillaries of the frog's tongue can be induced particularly with epinephrin. Capillaries in other regions may, however, be refractory towards epinephrin. He has also offered evidence to show that the normal tone is maintained by the presence of some constituent of blood plasma. This substance can be dialysed,

and it withstands heat. It bears many resemblances to pituitrin. There is also evidence of control through the nerves. Hooker in 1920 showed that the capillaries in the cat's ear become constricted by stimulation of the cervical sympathetic. The red area which becomes developed on the skin of man by drawing a pointed instrument along it is due to dilatation of both arterioles and capillaries, through a reflex action which is set up by the stimulation of the pain receptors.

The reflex arc in these cases involves the nerve centres in the spinal cord, since the reaction is abolished by cocainisation of the skin, or by section of the sensory nerves or roots. Irritation of the tongue of the frog is also followed by the development of a hyperaemic zone, but the reaction is not abolished by section of the lingual nerve, so that it cannot be a true reflex. On the other hand, it is abolished by cocainisation or by degeneration of the peripheral nerves, so that some form of so-called axon reflex must be involved. The response of the capillaries and arterioles to local stimuli varies greatly in different vascular areas, and in different species of animal. Capillaries also react toward changes in temperature, and they are sensitive to light. The erythema which is set up on the human skin by exposure to ultra-violet rays only disappears gradually and is followed by desquamation of the epidermis and by pigmentation.

*The Regulation of the Reaction of the Blood.*—This or its H-ion concentration (expressed as  $pH$ , or for convenience the negative exponent  $pH$ ) can be measured, either electrometrically (hydrogen electrode) or colorimetrically. In the latter method, the unclotted blood is placed in a small dialyser which is surrounded by a perfectly neutral ( $pH7$ ) isotonic saline solution. After a few minutes the solution assumes the same  $pH$  as the blood, and this can be measured by adding to it an indicator, such as phenol-sulphonephthalein, which changes in tint at a  $pH$  of about 7, and then comparing the tint with those produced in a series of phosphate solutions of varying, known  $pH$ 's, containing the same concentration of indicator. The colorimetric method gives a slightly higher  $pH$  (blood more alkaline) than the electrometric. While in the body arterial blood is slightly alkaline, its  $pH$  by the electrometric method being 7.35–7.4 and by the colorimetric 7.6. It is maintained practically constant, but it tends to become less alkaline (*i.e.*,  $pH$  lower) when large amounts of fixed acid enter it, as after violent muscular exercise (lactic acid) or in diabetes (oxybutyric and acetoacetic acids). This tendency is, however, compensated for by stimulation of the respiratory centre, so that  $CO_2$  is expelled from the blood in the lungs. The condition thus established is called *compensated acidosis*, and it is characterised by the blood being unable to take up as much  $CO_2$  as the normal, when exposed to various partial pressures of this gas. Its *alkaline reserve* is said to be lowered. When  $CO_2$  is deliberately blown off from the blood, by forced breathing, a relative excess of base comes to exist in the blood—*alkalosis*—so that an excess appears in the urine, making it alkaline in reaction. Both acidosis and alkalosis are associated with characteristic symptoms.

*The Oxygen and Carbon Dioxide of the Blood.*—For investigating the factors which govern the transport of  $CO_2$  and  $O_2$  by the blood, use is made of dissociation curves, which depict the relationship between the amounts of gas absorbed at various pressures. When  $CO_2$  is added to blood it combines with base (Na) in the plasma to form  $NaHCO_3$ . The Na is derived partly from NaCl and partly from Na-protein, thus:  $NaCl + H_2CO_3 = NaHCO_3 + HCl$ ; and  $Na\text{-protein} + H_2CO_3 = NaHCO_3 + H\text{-protein}$ . Since HCl cannot remain as such in the plasma it migrates through the envelopes of the red corpuscles to react in their interior with the potassium salts of phosphoric acid and haemoglobin thus:  $HCl + K_2HPO_4 = KH_2PO_4 + KCl$ ; and  $HCl + K\text{-haemoglobin} = KCl + H\text{-haemoglobin}$ . In virtue of these reactions the  $CO_2$  is absorbed without significant changes in  $pH$  (buffer action), and the plasma can take up considerably more  $CO_2$  when corpuscles are present than when they are absent. Pure plasma also absorbs  $CO_2$ , but in an entirely different manner from that of a solution of bicarbonate, because of the protein present in it (see above equation).

<sup>1</sup> A. V. Hill and his co-workers have also published numerous papers bearing on the physical aspects of muscular contraction, but the technical details are such that it is impossible to give a condensed account of the results.

When haemoglobin combines with oxygen, its acidity is increased so that it attracts more base and thereby liberates some  $\text{H}_2\text{CO}_3$  from bicarbonate. Consequently, the  $\text{CO}_2$  dissociation curve for arterial blood is lower than that for venous blood. Such a process occurs in the lungs, thus facilitating the removal from the venous blood of its  $\text{CO}_2$ . On the other hand, the loss of  $\text{O}_2$  from the blood, which occurs in the tissues, causes oxyhaemoglobin to be replaced by the less acid, reduced haemoglobin, so that the absorption of  $\text{CO}_2$  is facilitated by some base being set free. Not only do these changes in  $\text{O}_2$  content alter the  $\text{CO}_2$ -carrying power of the blood, but changes in  $\text{CO}_2$ , by affecting the pH, also influence the  $\text{O}_2$ -carrying power of the haemoglobin. The migration of  $\text{O}_2$  which occurs from the blood into the tissue cells in the capillaries is therefore due, not only to its attraction because of the low oxygen pressure in them, but also because  $\text{CO}_2$  migrates into the blood so as to lower pH.

A quantitative relationship therefore exists in blood among the following: (1) the free  $\text{O}_2$ ; (2) combined  $\text{O}_2$  (oxyhaemoglobin); (3) free  $\text{CO}_2$ ; (4) combined  $\text{CO}_2$  ( $\text{NaHCO}_3$ ); (5) pH; and (6) NaCl of plasma. L. J. Henderson, to whom much of our knowledge of the reaction of the body fluids is due, has shown that the relation existing among these six variables is such that if any two are known the remaining four can be computed, and he has expressed these relationships in graphical form.

**Mountain Sickness.**—Certain characteristic symptoms, known as mountain sickness, supervene at high altitudes. The importance of the problem does not depend on there being any particular practical value in knowing how to prevent the establishment of the condition, but rather because the general disturbance of the bodily mechanisms to which the symptoms are due furnishes an opportunity, by comparison with the normal, to determine the relative importance of certain physiological adaptations. It is now clearly recognised that reduction in the oxygen pressure, due to the rarefaction of the air, is the underlying cause of the symptoms, several features of which demand attention. The symptoms do not become developed during short stays in the rarefied atmosphere, and they are therefore not usually observed in short flights to great altitudes in flying-machines or balloons. They do not, as a rule, become acute on reaching a high elevation on a mountain by railway until after a day or so, unless muscular exertion is attempted. The acute symptoms are severe enough to incapacitate the individual, and they include headache, a sense of great fatigue, sleeplessness, often nausea and vomiting, with various circulatory and respiratory symptoms, including cyanosis. After one to four days the acute symptoms disappear but less definite ones remain, such as mental sluggishness, readiness to fatigue, breathlessness on moderate exertion, sleeplessness, etc.

In peoples who have lived for long at altitudes such as those obtaining in the Andes (14,000–16,000 ft.) the bodily functions are apparently quite normal, except that muscular exertion leads to breathlessness more readily than it should. There are also certain minor deviations from the normal, such as cyanosis (blueness), tendency to clubbed fingers and a change in the shape and the diameters of the thoracic cavity. The most significant feature of mountain sickness from the physiological standpoint is the disappearance of the acute symptoms after a few days' acclimatisation. In an Anglo-American expedition to Pike's Peak, under the leadership of J. S. Haldane, F.R.S., in 1912, the important conclusions were drawn: (1) that the symptoms are due to anoxaemia (that is, a subnormal pressure of oxygen in the blood supplying the tissues); and (2) that acclimatisation depends on increased breathing and on the development by the pulmonary epithelium of the power to secrete oxygen into the blood from the air in the lungs. Under physiological conditions at sea-level this secretion of oxygen does not take place, since diffusion is adequate to determine the passage of oxygen into the blood.

A more recent expedition (1921–2), under the direction of Mr. J. Barcroft, F.R.S., to the Peruvian Andes failed to obtain evidence of any secretion of oxygen by the pulmonary epithelium at an altitude of 14,000 feet. Acclimatisation was found to depend

on (1) an increase in lung ventilation, which raises the tension of oxygen in the pulmonary alveoli by 10–12 mm. and, therefore, also the tension in the arterial blood; (2) alteration in the power of the blood to absorb oxygen, so that at a given pressure of this gas a larger percentage is absorbed ( $\text{O}_2$ -dissociation curve); (3) decided increase in the percentage of red corpuscles, and therefore of haemoglobin, in the blood. The greater amount of haemoglobin increases the store of loosely bound oxygen carried into the capillaries, so that the venous blood is more saturated with oxygen than would otherwise be the case; but the chief advantage of this adaptation is a secondary one, the significance of which was demonstrated in subsequent experiments, in which it was found that when blood removed at sea-level was deprived of some of its  $\text{CO}_2$ , separated into plasma and corpuscles by centrifuging, and these two parts then recombined, so that the percentage of corpuscles was the same as that of persons acclimatised to rarefied air, the dissociation curve for  $\text{O}_2$  assumed the same form as in the blood of persons acclimatised to high altitudes. No decided alterations in the reaction of acclimatised blood could be detected, although the tension of  $\text{CO}_2$  in it, because of the hyperpnoea, was lower than at sea-level.

**The Function of the Parathyroid Gland.**—Removal of the four parathyroid glands is soon followed by the appearance of symptoms which are quickly fatal. The condition is called parathyroid tetany. Carnivorous animals are far more susceptible than herbivorous, and in the former substitution of the usual diet by one of milk and bread prevents the onset of the symptoms. Administration of calcium can also prevent their development. When one of the glands is left no acute symptoms may develop, although general nutritional disturbances gradually become evident, such as faulty development of the bones and teeth in young animals and a low assimilation limit for sugar. Two chemical changes in the blood have been found to be associated with parathyroid tetany: (1) a deficiency in the free calcium and (2) accumulation of guandin and its appearance in the urine.

The above symptoms may be removed by grafting a parathyroid gland from the same species of animal, thus suggesting an internal secretion, and Collip prepared from the glands an extract, *parathormone*, which is capable, when injected subcutaneously into parathyroidectomised dogs, of promptly removing the symptoms of tetany. After one injection the animals remain free of the symptoms for about 60 hours; but if the injections be repeated the animals may remain permanently free of them and the blood calcium rises to, or above, the normal level (10mg. %). Repeated injection of the extract into normal dogs also causes the blood calcium gradually to increase, and when a certain level (about 20mg. Ca. per 100 c.c. blood) has been reached characteristic symptoms supervene, consisting at first of weakness and hyperpyrexia and, later, of vomiting and diarrhoea, often accompanied by the appearance of blood in the vomitus and stools. The blood also becomes very viscid and darkly venous in colour, and the usually fatal outcome is probably due to a failure of the blood to circulate through the capillaries because of its stickiness. Herbivorous animals, such as mice, rabbits, guinea-pigs, do not show these symptoms on injecting parathormone (Macleod and Taylor).

**The Neuro-Muscular System.**—A valuable experimental analysis of the reflexes concerned in maintaining the position of the animal body while at rest and in movement has been contributed by Magnus. It will be recalled that a certain condition of extreme tonic contraction of the extensor muscles supervenes upon removal of the cerebrum (the decerebrate rigidity of Sherrington). It is now established, by the method of section at different levels of the brain, that the centre concerned is located in the medulla oblongata above the level of calamus scriptorius but below that of the red nucleus. This centre excites increased tone of the extensor musculature, and its effects are counteracted, in the intact animal, by impulses coming from another centre located in the red nucleus, which excites their antagonists, the flexors. When an animal in decerebrate rigidity is placed in the standing posture it can maintain this attitude, but it cannot retain it if disturbed.

On the other hand, if the section be anterior of the red nucleus, the animal can right itself if displaced from the standing posture. Working with preparations of these types Magnus and his co-workers have shown how reflexes initiated from different sense-organs, such as the labyrinth, the eyes and the proprioceptive nerves of the muscles, interact among one another to bring about the various postural reactions of the body. Magnus distinguishes between *static* and *stato-kinetic reflexes*. The former include the *postural reactions* when the body is at rest, and they may be reflexes of pose, in which the body remains fixed in a certain position; or *righting reflexes*, which are those which come into play to restore the pose after it has been disturbed. Stato-kinetic reflexes are produced by the actual movement of the body rather than the position which results from this movement. As an example of the methods employed in these studies, reference may be made to experiments illustrating tonic neck reflexes and tonic labyrinth reflexes. To demonstrate the former the labyrinth is removed in a decerebrate preparation, and it is found that when the head is moved so that certain of the neck muscles are put on the stretch and others relaxed the limbs assume definite positions which are characteristic for each position of the head, but which are not the same for the fore and hind limbs nor for those of opposite sides of the body. To demonstrate labyrinthine reflexes the labyrinths are left intact, and movements of the muscles of the neck are prevented by encasing the neck of the preparation in plaster of Paris. Variations in the orientation of the animal then result in poses of the limbs which are characteristic for each position, but in this case all four limbs behave alike. Destruction of the labyrinth abolishes these reactions.

**Glutathione.**—The very difficult problem of the mechanism of tissue oxidations has been considerably elucidated by the discovery of Sir F. Gowland Hopkins that a comparatively simple substance called *glutathione* can be prepared from various tissues, although not from the blood or connective tissues. Chemically, it is a depeptide of cysteine and glutamic acid, and it has recently been synthesised by Stewart and Tunnicliffe. In the reduced form its general formula may be written  $G\cdot SH$ , where  $G$  represents glutamic acid and  $SH$  cysteine. When it is oxidised the following reaction occurs:  $2 G\cdot SH \rightarrow G\cdot S\cdot S\cdot G + H_2$ . It is probable that a peroxide is formed during its oxidation, and if this occurs in the tissues the peroxide would be available for complete oxidation.

Much attention has also been given to the hypothesis of Wieland that the oxidation of the majority of substances consists essentially in the removal of hydrogen, rather than the addition of oxygen. As applied to tissue oxidations, this means that enzymes called hydrogentransportases act by transferring hydrogen from one oxidisable substance (hydrogen donor) to substances which become reduced (hydrogen acceptors). For many of the studies in this field methylen blue has been used as the acceptor, the speed of the reactions being measured by the time required to effect its decolorisation in vacuo.

**PIAVE:** see VITTORIO VENITO, BATTLE OF.

**PICASSO** (1881—), Spanish painter. Pablo Ruiz was born in Malaga, Spain; he took the name of his mother, Picasso. In his sixth year the family moved to Barcelona, where his father was a professor at the Academy of Arts, and where the son held his first exhibition. A Spaniard living and working in Paris, he is perhaps more typical of the present age, more deeply influenced by the uncertain and tortured spirit of the times, than any other painter alive. During the years 1906–12 he was associated with Georges Braque in developing Cubism, a method of painting which, in spite of excesses and debase-

ments, has definitely modified the world's conception of that art. In Picasso's Cubism painting for the first time becomes deliberately conscious of the new world of the machine, and of the modifications in the eye made by familiarity with all its complicated and exact patterns. The logical conclusion of his theory was a kind of painting which used form and colour not to imitate nature but to create a plastic world of its own that would have no connection with the world of nature, that would in fact be a pure and abstract art like mathematics. But Picasso abandoned Cubism before it reached that logical conclusion which his strain of Spanish mysticism had led him to visualise so differently. Herein lies the clue to his astoundingly fertile but unstable genius. Compared with Cézanne and El Greco, who were his most important masters, he lacks that staying quality, that capacity to endure, which is one of the requisites of great art. His sensory receptiveness is inexhaustible, but his creative power is limited by his lack of resistance. Since his desertion of Cubism, he has gone back to Ingres, and his recent work shows sheer virtuosity of draughtsmanship without any great emotional quality. Picasso's numerous works are mostly to be found in private collections. (See PAINTING.)

**BIBLIOGRAPHY.**—The fullest account of Picasso is found in Maurice Raynal's *Picasso* (1922). Other works are Guillaume Apollinaire, "Picasso," *La Plume* (May 1905); *Les peintres cubistes* (1913); Fritz Burger, *Cézanne und Hodler* (1913); Max Raphael, *Von Monet zu Picasso* (1913); Jan Gordon, *Modern French Painters* (1923); Paul Westheim, *Die Architektonik des Plastischen* (1923); Elie Faure, *History of Art* (1924).

**PICKERING, EDWARD CHARLES** (1846–1919), American physicist and astronomer (see 21.528), died at Cambridge, Mass., Feb. 3 1919.

**PICKFORD, MARY** (1893—), American motion picture actress, was born at Toronto, Canada, April 8 1893. She made her first appearance on the stage at the age of five with the local Valentine Stock Co., and when eight went on tour, playing the part of Jessie, the little mother, in *The Fatal Wedding*. She came to New York under the auspices of Belasco, creating the part of Betty Warren in *The Warrens of Virginia*. Her first motion picture work was undertaken with D. W. Griffith as an extra, but she returned for a time to Belasco, taking the part of Juliet in *A Good Little Devil* at the Republic Theatre in New York. In 1913 she came back to the screen with Famous Players Co. and rose to the first rank. In 1916 the Mary Pickford Film Corp. was organised and she received a salary higher than that paid to any other motion picture actress. In 1918 she became an independent producer and went to California. In 1919 she was the prime mover in the formation of the United Artists Corp. or "Big Four," composed of Miss Pickford, Charles Chaplin, Douglas Fairbanks and D. W. Griffith. Taking juvenile characters, Miss Pickford was for long the most popular screen actress in the world. Among the best known and most artistic of her pictures were *Tess of the Storm Country*, *Little Lord Fauntleroy* and *Dorothy Vernon of Haddon Hall*. She married Douglas Fairbanks, the motion picture actor and producer, March 28 1920.

**PIETERMARITZBURG**, Natal, S. Africa (see 21.592), had a population (1921) of 25,160 and with the suburbs of 36,023. Something like half (17,998) were whites. In 20 years the white population had increased by 3,400 only. Maritzburg, as it is commonly called, retains its pleasant, dignified character, has many fine public buildings, and is the religious, educational, professional and agricultural centre of Natal. Up to 1910 the Natal Parliament, abolished at the establishment of the Union, met here; it is now the meeting place of the provincial council, the seat of an Anglican bishop, and of the Natal division of the Supreme Court. University College is a constituent college of the University of South Africa. Its agricultural shows are noted for their excellence. Fort Napier, where thousands of German prisoners were interned during the World War, is now used as quarters for government and railway servants.

**PILNYAK** (1894—), Russian novelist. Boris Andreevich Vogau, who later took the pen name of Pilnyak, was born Sept. 29 1894 in Mojaisk, Moscow province. His childhood and early

youth were spent on the Volga and among the peasants and the land administration "intellectuals." He studied economics at the Moscow commercial institute and began publishing stories in 1915. During the Bolshevik revolution Piłsudski lived in Moscow and also travelled through Russia studying the new conditions. In 1923 he visited England and Germany. His works deal with the first chaotic stage of transition from the old Tsarist Russia to the "new world" of the Soviet Republic. He is the most prominent figure in post-revolutionary fiction. His sympathies are with the peasants as opposed to the town and his stories are deliberately fragmentary and read like diaries and chronicles.

**PIŁSUDSKI, JOSEPH** (1867— ), Polish soldier, was born in Nov. 1867 in Zulow (Zulowo), County of Vilna (Wilno) of an ancient family tracing their origin from the Lithuanian Princes of Ginet. He was educated at the Gymnasium of Wilno and attended the Medical Faculty at the University of Kharkov.

In 1887 Piłsudski was involved in an anti-Tsarist plot and sentenced to five years' penal servitude in Eastern Siberia, although the trial clearly established his innocence and his deprecation of terrorist methods. In his exile he learnt to know the Russians well. He returned to Wilno in 1892 and commenced his political activities there. As regards his convictions he was a Socialist, but he realised that a democratic State, free from political oppression was necessary in order to safeguard the natural development of the social system; consequently the political independence of Poland was introduced into the programme of the Polish Socialist party (P.S.P.) formed by him. "Romanticism of aims—realism of means"—that is how he described his creed and methods.

In 1894 he commenced the publication of the secret paper *Robotnik* (The Workman) and during the next ten years this paper voiced the most radical and outspoken opinions in Poland. *Robotnik* was edited, printed and distributed by Piłsudski himself. The risk of penal servitude for life did not deter him; wherever he went he inspired confidence and encouragement. His courage, keen sense of humour, attractive personality and good breeding made him the idol of the working classes; he was revered by the intelligentsia for the tenacity of his convictions, for his fearlessness and his iron will.

In 1894 he married Mlle. Marie Juszkiewicz; and assisted by his wife gradually increased the scope of his political activities. Armed resistance against the atrocities of the Russian Govt. was introduced into the programme of his party. Meetings and demonstrations were, in consequence, protected against the police and the military by armed detachments of workmen. Every year on May 1 blood flowed down the streets of Polish cities, reminding the nation that there were principles worth dying for by a "sudden and untimely death." In 1900 Piłsudski and his wife were arrested in the offices of the *Robotnik* in Łódź and for a year he was kept in a special cell in the notorious "Tenth Pavilion" of the Warsaw Citadel. In order to avoid a life sentence Piłsudski simulated insanity, and was, in consequence, transferred to the St. Nicholas Hospital in St. Petersburg (Leningrad). On May 13 1901 he was rescued, the result of an ingenious plot of the Polish Socialist party. He lived in London for some time and returned to Cracow in 1902.

Piłsudski's attention next became concentrated on the organisation of "armed resistance." Lack of munitions, however, frustrated his plans for an insurrection during the Russo-Japanese war. He went to Japan in order to enlist her support, but met with indifference from the Japanese Government. In spite of the failure of his mission, Piłsudski continued to organise his men by private means. After the Russian revolution of 1905 and the convocation of the Duma in St. Petersburg Polish revolutionary activities were discontinued, but the Russian Constitutional Govt. continued to pursue the policy of its predecessors with regard to Poland. Piłsudski transferred his headquarters to Cracow and Lwow and commenced his activities amongst the refugees from the Russian provinces of the country. The seemingly chimerical idea of a "private Polish army" was conceived there. An officers' school was established in Lwow

and branches of the "sharpshooters" (Strzelec) were formed throughout Galicia.

In a lecture delivered in Feb. 1914 before the Geographical Society in Paris, Piłsudski prophesied the imminence of the World War; he expressed the opinion that the ideal conclusion of such a war, from the Polish point of view, would be for Austria and Germany to conquer Russia, and for France to win a victory over Germany. True to his opinions, he sided with Austria when war broke out. The total strength of his "army" was 3,000 infantry and a squadron of cavalry insufficiently armed and equipped; the remaining 7,000 of his men were dispatched to Hungary by the Austrian general command. Piłsudski resisted vigorously every attempt of the Central Powers to employ his own legions outside the frontiers of Poland. When, in Nov. 1914, the Germans attempted to send the legions over to the Western front, he broke through the Russian columns and, in disobedience to Austrian orders, returned to Cracow. His brigade took part in numerous battles in which it exhibited great bravery and exemplary discipline. As a leader of his troops Piłsudski was unsurpassed. Calm, brave, simple and devoted to his men, he became the idol of his subordinates. His mere presence in the trenches inspired the troops with the hope for glory and a certainty of victory.

When, after the collapse of the Brusilov offensive, Russia was virtually conquered, Piłsudski turned against the remaining partition Powers; i.e., Germany and Austria. In July 1916 he resigned the command of the Polish legions in consequence of the abuses of the German and Austrian occupation authorities in Polish territory. At the same time he sought to establish relations with France and Great Britain through his colleagues, MM. Sokolnicki and Narutowicz. His attitude, which was quite natural, was, however, met with distrust by the Allied Powers. On Nov. 5 1916 the independence of Poland was proclaimed by the Central Powers and Piłsudski accepted the position of Minister of War in the newly formed Council of State. Within a short time he formed the semi-secret Polish military organisation, i.e., Polska organizacja wojskowa ("P.O.W."), which spread throughout the country and was instrumental in disarming Germans and Austrians in 1918.

When the Polish legions in Russia, commanded by Gen. Musnicki, proclaimed Piłsudski their spiritual leader, and when his own legions refused, in July 1917, to take the oath of "fraternity of arms with Germany and Austria," Piłsudski was arrested by the Germans and imprisoned with his chief-of-staff Gen. Sosnowski in the fortress of Magdeburg, whence he was released in 1918 by the German revolutionary authorities. He arrived in Warsaw on Nov. 4 and completed the disarmament of the armies of occupation. The Regency Council, established by the Germans, resigned in his favour and all military organisations in the country submitted to his command. An efficient and disciplined army was soon formed. With this army Piłsudski maintained the independence of Poland, which was menaced on all frontiers by the Bolsheviks, Lithuanians, Ukrainians, Czechs, and Germans (in Silesia) and laid the foundations of a strong, democratic State. Vested with dictatorial powers, he, like a modern Washington, summoned the Constituent Diet elected by general ballot. He gave his country everything which he thought was necessary for its constitutional development; like a lion he guarded its inviolability and its prestige. His great mind, his sense of justice, his deep and disinterested love for his country gained for him the admiration of his people. His election as Chief-of-State was unanimous; and the army conferred upon him the supreme honour of First Marshal of Poland.

In foreign politics Marshal Piłsudski proved himself to be a cautious and far-seeing statesman. His military genius was exhibited particularly during the war of 1920. Believing that Poland ought to pursue the traditions of its "golden age" (14th, 15th and 16th centuries), he undertook the expedition to Kiev in 1920. He captured Kiev in order to hand it over to Poland's ally the Ukraine, in the same way as he took Dunaburg to hand it over to Latvia. Unfortunately, the Ukrainians were too weak to take advantage of Piłsudski's victories; his plans for

a Polish-Ukrainian Federation failed and the Polish troops retreated from Kiev. The strategic aim was, however, achieved; the southern flank of the Russian army which was to attack Lwów and the oilfields was completely disorganised, and thus the Bolsheviks were forced to attack from the north. Their numerical superiority gave them initial advantages. Disregarding the opinions of all his military advisers, Pilsudski concentrated along the River Wieprz his devoted regiments and by a lightning attack, which he led himself, broke through the Russian front and dispersed the Bolshevik hordes collected round Warsaw, where they expected an "easy victory." Pilsudski's victory saved not only Poland but the whole of Europe from a new war and conflagration.

Personally modest, although grand in his ideas, Joseph Pilsudski retired from public life when he became aware that his actions and advice evoked distrust and intensified party feeling. His retirement did not weaken factional wrangling, however. On the contrary it intensified the decay of Parliamentary life and multiplied cases of administrative corruption. When this trend of events became a menace to the Republic, Marshal Pilsudski came to the conclusion that, as the creator and spiritual leader of the modern Polish state, he could no longer remain inactive. Supported by his devoted army, he demanded the strengthening of the authority of the President, a greater measure of Government independence from a faction-ridden Parliament and the impeachment of all persons guilty of corruption, regardless of their standing or party support.

Marshal Pilsudski's opponents succeeded in gaining the formal support of Wojciechowski, President of the Republic. The military demonstration undertaken by the Marshal on May 12 developed into a three days' army conflict in the streets of Warsaw resulting in the resignation of the President. The National Assembly, convoked by his successor, Monsieur Rataj, marshal of the diet, elected, by a great majority, a new President in the person of Joseph Pilsudski. The results of the election were hailed with tremendous enthusiasm throughout the whole country, particularly among the peasant and working classes. Pilsudski, however, desirous of devoting himself entirely to the army, did not accept the high office and recommended Prof. Ignacz Mosięski as the most suitable candidate. The latter was elected President and called upon Monsieur Bartel to form a Government which would undertake internal reforms on the lines proposed by Pilsudski. The Marshal himself accepted the office of Minister of War and chairman of the Supreme Army Council. (W. St.)

**PIRANDELLO, LUIGI** (1867– ), Italian dramatist and novelist, was born June 28 1867 on a country estate near Girgenti (Sicily). He first went to Rome at the age of 19, staying there until 1891, when he went to Germany and graduated in philosophy at the University of Bonn. He subsequently returned to Rome and taught at the girls' high school until 1923. His first literary essays were in verse, a volume entitled *Mal giocando* published in 1889, followed by a poem *Pasqua di Gea* (1891) and *Elegie renane* (1895). Another Sicilian writer, Luigi Capuana, persuaded him to devote himself to fiction, and in 1894 he published his first novel, *L'esclusa*, in which his somewhat bitter realism already finds expression. Besides the comic novel, *Il turno*, he began to publish short stories in ever-increasing numbers, the somewhat painful humour of which soon attracted public attention: *Amori senza amore* (1894), *Quando ero matto* (1903), *Befte della morte e della vita* (1902, 1903), *Bianche e nere* (1904), etc. In 1904 his most celebrated novel, *Il fu Mattia Pascal*, appeared, the story of a man, who having shammed being dead, tries in vain to begin his life anew in a different atmosphere and under another name, but fails lamentably. Other collections of short stories followed: *Erma bifronte* (1906), *La Vita Nuda* (1910), *Terzetti* (1912). He set forth his artistic creed in two volumes entitled *Arte e scienza* (1908). In 1913 his novel, *I vecchi e i giovani*, describing the drama of Italian life after the Risorgimento, was published in the *Rassegna contemporanea*. Other volumes of short stories appeared between 1914 and 1926, such as *La trappola* (1915), *Un cavallo nella luna* (1918), *Il carnevale dei morti* (1919), *Tu ridi* (1920),

and another novel *Uno, nessuno e centomila* was published in the *Fiera letteraria*.

In 1920 he said of his own art:—

I think that life is a very sad piece of buffoonery; because we have in ourselves, without being able to know why, wherefore or whence, the need to deceive ourselves constantly by creating a reality (one for each and never the same for all), which from time to time is discovered to be vain and illusory. . . . My art is full of bitter compassion for all those who deceive themselves; but this compassion cannot fail to be followed by the ferocious derision of destiny which condemns man to deception.

This despairing outlook attained its most vigorous expression in Pirandello's plays. In his youth he had shown a certain contempt for the drama, but in 1912 he was persuaded by the Sicilian playwright, Nino Martoglio, to dramatise one of his own short stories, *La Morsa*, as a one-act piece. His first three-act comedy, *Se non così* (1917), was produced by Marco Parga at Milan in 1913; and then many plays—dramas and comedies—of which the most celebrated are *Il berretto a sonagli*, *Liola* (1917), *Così è se vi pare* (1918), *L'uomo, la bestia e la virtù* (1918), *Ma non è una cosa seria*, *Come prima, meglio di prima*, *Sei personaggi in cerca d'autore*, *L'imbecille*, *Enrico IV.*, *Vestire gli ignudi* (1918), *La vita che ti diedi*, *L'altro figlio*, *Ciascuno a suo modo*, *La sagra del signore della nave*, *La giara*.

Pirandello's dramatic art was at first criticised for being too "cerebral," for not seeing life as it really is and for arbitrarily deforming it. The Roman critics first discovered the real meaning of Pirandello's ideology and the human sense of his plays. His main themes are: the necessity and the vanity of illusion, the multiform appearances, all of them unreal, of what is presumed to be the truth, man is not what he thinks he is, but he is "one, no one and a hundred thousand," accordingly as he appears to this person or to that, and is always different from what he creates himself in his own mind. Hence the supreme catastrophe, when a moral looking-glass suddenly reveals to him the image of himself which others see, i.e., what he is to others. Most of Pirandello's plays deal with a lower middle class milieu, peopled with clerks, teachers, lodging-house keepers, etc., from whose modest vicissitudes he draws conclusions of vast human significance. Typical is *Così è se vi pare*, in which he proves that it is impossible to know the real truth. *Enrico IV.* develops in a broader sense; that is, a drama in which we have a man who renounces his changing, empty and vain existence to play the part of a madman, and pretends to believe himself an historical personage, Henry IV. All this might be merely theatrical trickery if it were not seared by a deep anguish, characterising a philosophy which has destroyed all faith in the absolute, in reality, in any fixed limits outside individual personality.

Pirandello's plays have rapidly achieved success throughout Italy and abroad, and have been translated into some 15 languages. In 1925 he created an art theatre of his own in Rome, where new Italian and foreign plays are performed, and in the summer of the same year he brought his company on a tour to England to produce his own plays in London (at the New Oxford Theatre), to Paris, Basle and 18 theatres in Germany. Everywhere he met with an enthusiastic reception. (S. D'A.)

**PIRENNE, HENRI** (1862– ), Belgian historian, was born at Verviers Dec. 23 1862. He first lectured at the University of Liège, and in 1886 became professor at the University of Ghent. His most famous work, *Histoire de Belgique*, of which five volumes had appeared in 1925, completely revolutionised the current conceptions of Belgian history and nationality. Starting from the origins, M. Pirenne showed how, from the time of the Germanic invasions, Flemings and Walloons were drawn together by community of tradition and economic interest: the unity achieved in the 15th century under the dukes of Burgundy was not the result of a foreign domination, but of the natural development into a modern nation of the various fiefs, among which Belgium was divided in the Middle Ages. When the Belgian provinces came under foreign rule during the following centuries, their local liberties were jealously preserved by the people, until their complete independence was recognised by the Powers in 1830.

M. Pirenne became chiefly known among historians as a mediaevalist, and his works on mediaeval cities and social conditions include *Les anciennes démocraties des Pays-Bas* (Paris, 1910, Eng. tr. 1915) *Recueil des documents relatifs à l'histoire de l'industrie drapière en Flandre* (with G. Espinas, 4 vol. 1906-24) and *Mediaeval Cities: Their Origins and the Revival of Trade* (Princeton, 1925). M. Pirenne was the first president of the "Union Académique Internationale" (1920-3) and received honorary degrees from the universities of Brussels, Oxford, Manchester, Groningen, Paris, Strasbourg, Bordeaux, Leipzig and Tübingen. (See ALBERT, KING OF THE BELGIANS; BELGIUM.)

**PISTOL** (see 21.654).—During the period 1910-26 the automatic pistol has been gradually perfected and adapted to replace the revolver as a military side arm, despite the fact that there are many who maintain that the revolver is the more dependable

and revolver was extended to include many branches of the service not armed with rifles, particularly by the United States, British and German armies. The large calibre weapons of the former armies gave them a great advantage in pistol fighting, and their use confirmed previous opinions that a large calibre heavy bullet of short range and low velocity is more effective in a pistol than a high velocity, small calibre bullet. The principal and best known systems of automatic pistols, most of which are manufactured in several calibres, include the following: Colt, Browning, Webley, Savage, Remington, Luger, Mauser, Mannlicher and Steyr.

Automatic pistols have now been adopted by the armies of the United States, Belgium, Spain, Italy, Denmark, Portugal, Switzerland, Germany and Austria. The British Navy has adopted the Webley automatic pistol.

*Automatic Pistols and Their Cartridges*

| Cartridge                                                                                                                                                                                         | Barrel Length, Inches | Weight of Bullet, Grains | Muzzle Velocity, Ft. (H. O'L.)

weapon. The automatic pistol, like all complicated mechanisms, occasionally malfunctions, usually due to a defective magazine or cartridge. This disadvantage is, however, offset by the fact that from the pistol about three times the number of shots per minute may be fired as from a revolver; its magazines are changed instantly, thus giving sustained fire while loaded magazines are at hand. This gives a great advantage to the user of a properly working pistol, as a revolver is often useless at close quarters, such as obtained in trench raids, after its six shots have been fired. In such positions the volume of fire from a group of pistols is much greater than that from an equal number of revolvers even if a pistol is occasionally disabled by a jam.

Owing to its simpler mechanism, the revolver is more reliable for civilian self-defence where more than two or three shots are seldom required; the weapon then being unused and often neglected for long periods. The revolver is also considered superior to the automatic pistol in safety. In the latter, the loaded cartridge automatically inserted in the chamber after each shot is liable to be forgotten and left there when the magazine is taken out. To prevent accidental discharge from this source, some of the newer models have a "magazine safety," which prevents the pistol from being fired when the magazine is out. In addition, a "grip safety," which prevents discharge unless the rear part of the grip is pressed in at the same time the trigger is pulled; and a safety catch, which locks the slide and hammer, are often used. Recent models of revolvers show no improvements of note, and it is probable that with the attention now being given to the design of the automatic pistol, that weapon will eventually be made as reliable, safe and quick to get into action as a good revolver.

In European armies previous to the World War, the pistol was used almost exclusively as an officer's side arm. Their weapons were of small calibre, ranging from 7.63 mm. to 9 mm., and lacked stopping power. During the War the use of the pistol

**PITCH:** see COAL TAR PRODUCTS.

**PITTSBURGH, PA.** (see 21.678), had (U.S. Census, 1920) a population of 588,343, increased in 1925 to 631,563. The increase over 1910 was 54,288 or 10.2%. After the 1920 census was taken, St. Clair borough and parts of Chartiers, Reserve and Lower St. Clair townships were annexed. Within the metropolitan district of a 10-m. radius, but outside the city limits proper, there was a further population equal in number to that within the municipality itself, and within a radius of 30 m. the total population was 1,800,000. In Allegheny co., of which Pittsburgh is the county seat and business centre, there were in 1920 1,184,832 persons (1,252,344 in 1925), 13.6% of the total population of Pennsylvania.

*Recent Developments.*—The 50th anniversary of Pittsburgh, elaborately observed in 1908, marked the beginning of a new period of corporate, educational, social and material development. By legislative enactment (1911) the former common and select councils gave way to a small council of nine members, elected by general vote of the entire city. The mayor continued to appoint the heads of departments (safety, works, health, charities, supplies, property, water, treasury). The comptroller also was elected as formerly by popular vote. The expansion of public business in the city and county exceeding the capacity of the city hall and the court-house led to the erection by joint action of a new city-county building, a fine structure of nine storeys. The county in 1923 completed a twin tunnel—each tube 25 ft. wide and 5,880 ft. long at a cost of \$6,000,000—under Mt. Washington to connect the southern hill district with the city by a high-level bridge over the Monongahela river bringing that district within 15 minutes' transit of the centre of the city. Two new bridges across the Allegheny were completed in 1925, and two others under construction were expected to reach completion in 1926, thus providing the city with 16 bridges across the two magnificent rivers.

The value of Pittsburgh products in 1923 was \$1,883,447,400, being 21.8% of those for the entire state. In 1924 the city held fifth place in bank clearings (\$8,036,969,343) and first place in the following manufactured products: iron, steel, glass, electrical machinery, steel cars, tin plate, air brakes, fire-brick, white lead, pickles and preserves, corks, aluminum, railway signals and safety devices, vanadium, bituminous coal and coke.

In 1911 the Legislature adopted a new school code for the entire commonwealth, coming into operation on Nov. 11 1911. Under this code a Board of Education consisting of 15 members appointed by the Common Pleas judges took control. Separate school districts were abolished; a new city superintendent with associate superintendents were appointed; the scattered and unrelated school agencies were consolidated: new high schools and junior high schools established. New ward schools were erected. Between 1920 and 1925 eight new high schools were built and eight grade schools. The public-school system was supplemented by parochial schools. In addition to the high schools there are a number of academies and other schools, 77 in all, on private foundation. The recent development of higher education has been notable. The University of Pittsburgh raised \$7,000,000 toward the erection of a 52-storey Cathedral of Learning; completed the Stadium and in 1921-3 added 32 ac. to the campus. The Carnegie Institute continued its service to the community through its central library. In the Institute is held each year an international exhibition of contemporaneous paintings. Pittsburgh has altogether 20 hospitals, modern in construction and equipment, with 4,500 beds. There are 196 clubs, 511 churches, 263 social and welfare agencies, 50 playgrounds and 28 parks.

A city planning commission and board of appeals control the height and character of all buildings. A bureau of traffic relief and a traffic commission were created in 1924 and, in the following year, a dept. of city transit charged with the regulation of traffic conditions and with the matter of recommending subways and a comprehensive system of rapid-transit lines for the entire city. (S. B. McC.)

**PIUS X.** (1835-1914).—Although the pontificate of Pius X. (see 21.600) lasted only 11 years (Aug. 4 1903-Aug. 20 1914), it has been said that his work for the Church, reconstructive and reformative, surpassed that of any of his predecessors since the days of Sixtus V., who died in 1590. In the defence of the faith, his condemnation of the 65 propositions of Modernism in 1907 will rank as a parallel to the condemnation of the 68 propositions of Molinism by Innocent XI. in 1637 or the 101 propositions of Jansenism condemned by Clement XI. in 1713.

The activity of the pontificate may be judged by the fact that its output of papal Bulls and greater official papal documents (counting only those published) exceeded 3,322. These bear upon undertakings and reforms of the first importance—the codification of canon law; the protection of the liberty of the conclave by the abolition of the exclusiva; the simplification and security of the conditions of marriage by the *ne temere* legislation; the restoration of the Rota as the supreme court of appeal; the regulation of the triennial or quinquennial visits of bishops to Rome; the legislation as to church music; and the decree as to first communion, and the encouragement of international eucharistic congresses; the reform of the Roman breviary; the founding of the biblical institute for the work of Scriptural research; the regulation of studies in the seminaries; the creation of the commission for the great work of editing the true text of the Vulgate; the reconstruction of the official machinery of the Roman curia; the transfer of the English-speaking countries from the propaganda or missionary régime to the normal government of the Church. To these may be added in the domain of discipline the unflinching vindication by Pius X. of the Church's right to depose delinquent bishops, carried out even at the cost of rupture of diplomatic relations with France; an apostolic visitation rigorously carried out through the dioceses of Italy, resulting in four bishops being made to resign on account of

neglect or inefficiency; a further regulation by which no one can be proposed for a bishopric unless his promotion receives the visa of the Holy Office, which means that his past life has been free from ecclesiastical censure or reproach.

The well-known personal characteristics of Pius X. were his piety, charity, deep humility, simplicity, pastoral zeal, combined with great charm of manner to all who approached him. For war he had nothing but horror and it was the shock of the outbreak of the World War that hastened his death, which took place in Rome Aug. 20 1914. It is said that one of his last acts was to refuse the request of the Austrian Emperor to bless his cause, saying, "I do not bless war: I bless peace." (J. Mo.)\*

**PIUS XI.** (1857- ), Pope since 1922, was born on May 31 1857 at Desio, a small town north of Monza, in the environs of Milan, on the road to Como, and was named Ambrose Damien Achille. His father was Francesco Ratti, the manager of one of the great silk factories of Desio, and partner in the firm of Gadda. Achille was educated at the seminaries of San Pietro Martire and of Monza, and at the college of St. Charles at Milan, where he graduated. Feeling that he was called to the priesthood, he studied for two years in the greater seminary. His life at this time was profoundly influenced by his spending his vacation months with his uncle, Don Rodolpho, the venerable and exemplary parish priest, and provost of Asso, a village in the promontory of the Bellagio. From his windows he could see Lake Como and the Alps, of which later on he was so strongly to feel the lure. It was also here that he came under the personal notice of the Archbishop of Milan, Mgr. Nazario di Cabileana, who was staying as the guest of Count de Herra, and was a frequent visitor at his uncle's presbytery. The Archbishop was much struck by the future Pope's earnestness and maturity of judgment, and was wont to call him his "young old man." Ever afterwards he took a deep interest in his career. He sent him to the college of St. Martin and then to Rome to study at the Lombard College and attend the lectures at the Gregorian University. Here Achille Ratti took with distinction the degrees of doctor of philosophy, of theology and canon law. He was ordained priest on Dec. 20 1879.

At the Lombard College his fellow student and closest friend was Alessandro Luaildi, later Cardinal Archbishop of Palermo. These two were mentioned to the Pope by Professor Liberatore as the most brilliant of his students. They were the first to win the doctorate at the Angelico, the new Thomistic College founded by Leo XIII. at Rome. The Pope sent for the two students and while passing through the Clementine Hall, from his chair in which he was being carried to the Vatican gardens he delivered to them an impressive lecture upon the vital importance of a sound philosophy and of their mission in promoting it in the years which lay before them. In 1882 Dr. Ratti returned to Milan and was appointed for some months to a curacy at the village of Barni.

Following up the intentions of Leo XIII., the Archbishop transferred him to the Great Seminary, where he filled for five years the post of professor of dogmatic theology. In 1888 he was admitted as a member of the college of doctors at the great Ambrosian Library. This appointment gave a new direction to his scholarship. In this task, Dr. Ratti found a congenial field of labour under the guidance of the prefect of the college, the learned Abbate Cerriani. He became an expert, especially in Latin palaeography and published several studies, and contributed numerous articles to the learned reviews. In 1907 he succeeded Cerriani as prefect of the library. He was made domestic prelate by Pius X. and canon of the Milan Cathedral by Cardinal Ferrari. During the years 1905-7 he undertook and carried out a reclassification of the library upon modern methods so as to facilitate the work of consultation and research. His success in this enterprise was recognised by the King of Italy, who bestowed on him the knighthood of the Order of Saints Maurice and Lazarus.

From 1888 onwards he was chaplain and director to the nuns of the Cenacle, an order specially devoted to the work of arranging spiritual retreats or conferences for all classes of women.

At their convent he was brought into contact with all that was most distinguished and zealous among the laity of Milan and became an active organiser of their manifold works of charity. At the same time, he spent the hours that he could spare from his library in teaching the catechism to numbers of poor children, including the little chimney sweeps that annually come down from the Tirol. He clung to this work during the 30 years that he remained in Milan.

He more than once visited England. In June 1900 he stayed for a time with his intimate friend, Bishop Casartelli, at Manchester. He studied at the Bodleian in Oxford and at the British Museum and said Mass in Westminster Cathedral. In his summer vacations it was his custom to make climbing excursions in the Alps. The *Bolletino* of the Italian Alpine Club relates how, in 1889, he discovered a new way of ascent by the eastern slope to Monte Rosa, and how on one occasion by his courage and promptitude he saved the life of his guide. The ascent is commemorated by a monument erected by the club at Macugnaga. In 1908, during the riots at Milan, he was active in pacifying the turbulent elements and intervened successfully to save the Capucine convent from destruction during the bombardment.

Cardinal Ferrari had made him his trusted counsellor in the government of the diocese and in 1909 appointed him to a canonry in the cathedral. In 1912 Pius X. called him to Rome, made him vice-prefect of the Vatican library (where he served under Cardinal Gasquet) and at the same time promoted him to a canonry of St. Peter's. On the succession of Benedict XV. he became the familiar friend of the new Pope, who, with a keen appreciation of his qualities singled him out for the diplomatic service and entrusted him with the delicate mission of Apostolic Visitor to the new republic of Poland. Here his clear judgment and tact and his fluent knowledge of German and Polish enabled him to achieve a marked success in dealing with the complicated claims of the various nationalities in Poland and the bordering Russian territories. It is related that he himself had shrunk from this task and pleaded for a whole hour with the Pope to be excused from it. Benedict XV. only listened in silence and simply asked at the end "How soon can you start?" and Mgr. Ratti's only reply was simply "Tomorrow."

In June 1919 Ratti was made Nuncio Apostolic in Poland and titular Archbishop of Lepanto and on July 3 was consecrated in Warsaw by the Archbishop, Mgr. Katowski. It was a mark of the confidence reposed in him by all classes that he was chosen by the Interallied Commission to act as high ecclesiastical commissioner for the plebiscite of Upper Silesia by agreement of both the Polish and German Governments. During the Bolshevik invasion, when most of the embassies withdrew from Warsaw, the Nuncio remained and carried on his work of conciliation and of succour for the poor in devastated regions. Pope Benedict XV. sent him the pallium, the Polish Govt. decorated him with the Order of the White Eagle and the university enrolled him amongst its doctors. On the death of Cardinal Ferrari, Benedict XV., in June 1921, appointed him Archbishop of Milan, and made him a Cardinal under the title of S.S. Silvestro and Martino ai Monti. On Sept. 2 he returned from a pilgrimage to Lourdes and on the following day was solemnly enthroned. Milan gave him an enthusiastic reception. His carriage was drawn by the people and was accompanied by the civic authorities and the military and clergy. The vast procession was enhanced by the novel feature of an escort of aeroplanes encircling above it along the route to the Cathedral.

Pope Benedict XV. died on Jan. 22 1922. On Feb. 2 the Cardinals entered into conclave and on Feb. 6 Cardinal Ratti was elected Pope. He chose the name of Pius XI. and was proclaimed from the balcony of St. Peter's. He received the triple obedience of the Cardinals and on Feb. 11 was crowned in the presence of an enormous concourse in the Basilica. Since then the life of Pius XI. may be summed up as one of constant activity, in which his encouragement of all high ideals and good

works has been marked by staunchness in matters of principle and the spirit of pacification and conciliation in administration. During 1925, the year of the jubilee, he was brought, perhaps more than any other pontiff, into personal contact with his spiritual subjects by receiving more than 1,250,000 pilgrims from all parts of the Catholic world. By all he is revered for his learning, his charity, piety and width of sympathy, his courtesy, tact and charm of deportment and, most of all, for his untiring devotion to the duties of his exalted pastorate.

**BIBLIOGRAPHY.**—He has published *Climbs on Alpine Peaks*, transl. by J. E. C. Eaton, with introd. by Bishop L. C. Casartelli and a foreword by Douglas W. Freshfield. See also *Annuaire Catholique* (1923), ed. by Mgr. A. Baudrillart; *Acta Apostolicae Sedis. Commentarium Officiale* (1919-25); and *Documentation Catholique* (1922-6). (J. Mo.\*)

**PLAGUE** (see 21.693).—The investigations of the Indian plague commission working in conjunction with the advisory committee showed that bubonic and septicaemic plague are transmitted by the agency of fleas. Highly susceptible animals are not infected by their plague-stricken fellows so long as fleas are excluded from the cages, but with the introduction of these ectoparasites the disease forthwith spreads from the sick to the healthy. Subsequent experience has confirmed the main findings of the commission, and outbreaks of human plague are unquestionably mere extensions of preceding or concurrent plague affecting animals. Rats (*Rattus rattus*) are of outstanding importance as reservoirs of infection through their close association with man, but marmots (*Arctomys bobac*), gerbilles (*Tatera lovengulæ*) and ground squirrels (*Citellus beecheyi*) have been responsible for epidemic outbreaks in China, South Africa and California respectively.

**Mode of Infection.**—The plague commission concluded that the disease can be transmitted by the faeces of infected fleas, but did not state that this is the usual method of spread. Bacot and Martin later demonstrated that the entrance to the flea's stomach becomes obstructed by a mass of plague bacilli. Such fleas in their persistent efforts to feed merely succeed in distending the gullet with blood, which, now contaminated, regurgitates on to the skin of the host. The organisms then enter the body either through the flea's bite or through some abrasion of the skin.

**Fleas as Vectors.**—The flea most commonly incriminated as a plague-vector is *Xenopsylla cheopis*, but several other species of rat fleas (*Ceratophyllus fasciatus*, *Stivalius ahalae*), the common mouse flea (*Leptopsylla musculi*), the dog flea (*Ctenocephalus canis*), a marmot flea (*Ceratophyllus silantiewi*) and the human flea (*Pulex irritans*), amongst others, are proven carriers of plague that are known to bite man. When the plague commission made their investigations only one species of *Xenopsylla* (*X. cheopis*) had been recognised, and they were unaware that two other species of this genus commonly infest Indian rats. One of these, *X. astia*, is incapable of conveying plague in circumstances where transmission by *X. cheopis* is readily effected. *X. astia* is the predominating species infesting rats in parts of India which have remained free from plague, or where plague when introduced has not spread. The inhospitality of *X. astia* to the plague bacillus may be the responsible factor in such immunity, as was first suggested by Hirst in 1914.

**Epidemiology.**—Laborious studies on the biology of fleas have added to our knowledge of the epidemiology of plague. These insects cannot withstand desiccation, and their survival apart from their host is proportional to the rate at which they lose moisture. Bacot and Martin (1924) found the water content of fleas to be 80% of their weight, and death occurred before the loss of water had reached 60% of their weight. This goes far to explain the observation that plague does not maintain itself in epidemic form when the temperature rises above 80° F., accompanied by a saturation deficiency of over .30 of an inch; whereas Bacot (1914) demonstrated that starved rat fleas (*C. fasciatus*) infected with plague may remain alive, and infective, for one or two months in cool weather. He also showed that the larval and pupal stages may be prolonged by natural agencies, and in consequence active adult fleas may be found, in favourable

situations, where there have been no hosts for long periods—10 months in the case of *X. cheopis*, and 22 months in that of *C. fasciatus*. The seasonal variations in the prevalence of plague have been recognised for many centuries. In temperate countries epidemics attain their maximum in the summer months, whereas in tropical climates the onset of hot, dry weather brings an existing epidemic to an end. In each case, the peak of the plague curve coincides with meteorological conditions most favourable to the activity and longevity of fleas. In contradistinction to the foregoing, pneumonic plague, once established, spreads independently of animals and fleas. In outbreaks of ordinary plague, a secondary involvement of the lungs supervenes in a small proportion of cases, and if atmospheric and environmental conditions favour the survival and transmission of the bacilli an epidemic of pneumonic plague may result, the virus being transmitted from the cougher to the victim up to a range of about three feet.

**Treatment.**—Unfortunately, there is no plague specific. Serum, to be really effective, must be given before the symptoms of the disease are manifest, an impossible procedure in most cases. Still, when available, serum should be administered intravenously in doses of 80–100 c.c.'s, and repeated. Some advocate injection of tincture of iodine (7–10 minims), or other antiseptics, intravenously, and also into the buboes. These measures are of doubtful benefit. Buboes showing signs of suppuration should be incised. Otherwise, treatment is on general lines, and cardiac stimulants should be administered early.

**Prophylaxis.**—So long as members of a community are content to live in association with rats and fleas correlative plague is a likely result. Meanwhile, plague prophylaxis consists mainly of warfare against rats, in the hope of ultimately banishing them from human habitations and from contact with man. Any general elimination of these pests over wide areas is a slow, costly and usually impracticable affair, and all that can be achieved in most cases is some degree of palliation by rat-proofing of grain stores, wharves and other places which serve as centres for the dissemination of plague. Destruction of rats by trapping and poisoning is a commendable procedure, but of itself will never eradicate endemic plague, for the losses in the rat population are quickly made good if survivors are provided with food and harbourage. An important measure of personal prophylaxis is inoculation with anti-plague vaccine, which affords a good degree of protection. Persons entering plague-infected houses should wear gaiters, and otherwise render their clothing as flea-proof as possible; if there is any suspicion of pneumonic plague, goggles, and masks made of several layers of fine gauze, should be worn without fail.

**BIBLIOGRAPHY.**—*Journal of Hygiene, Plague Supplements* (1912–7); League of Nations Report, ch. 130, *Prevalence of Epidemic Disease in the Far East* (Geneva, 1923); Ministry of Health, Report 19, *Hydrogen Cyanide for Fumigation Purposes* (1923).

**PLANCK, MAX** (1858– ), German physicist, was born at Kiel April 23 1858. He studied at the universities of Munich and Berlin, became an assistant in Munich University, and was subsequently appointed a professor in Kiel (1885) and in Berlin (1889). Planck devoted himself to the study of theoretical physics, and in particular to that of thermodynamics. His lectures on this subject appeared in book form and were translated into English, French and Russian. He gained international fame by his *Law of Radiation* (1901), which asserts that the energy of radiation is emitted and absorbed in integral multiples of certain indivisible “quanta” of energy, which depend on the frequency of oscillation of the electrons. In 1912 Planck extended this “quantum theory” to all kinds of energy and added the assumption that only emission proceeds discontinuously, in quanta, while absorption is continuous. In 1913 he somewhat altered his theory, but subsequently reinstated the old conception. Although several physical phenomena, such as the properties of the specific heats of solids, the kinetic theory of gases, confirm Planck's theory, it is still warmly disputed. In 1918 he was awarded the Nobel Prize for physics. Planck became editor of the *Annalen der Physik*.

Among his works are: *Die Entstehung und bisherige Entwicklung der Quantentheorie* (1920), transl. by H. T. Clarke and L. Silberstein (1922); *Vorlesungen über die Theorie der Wärmestrahlung* (1921); *Physikalische Rundblicke* (1922), transl. by R. Jones and D. H. Williams (1925); *Einführung in die Theorie der Elektrizität und des Magnetismus* (1922); and *Die Ableitung des Strahlungsgesetzes* (1923).

**PLANQUETTE, ROBERT** (1850–1903), French musical composer (see 21.725), died in Paris Jan. 28 1903.

**PLANT PATHOLOGY.**—The progress made in the theoretical and practical study of plant pathological problems during the early part of the century consisted not of any very outstanding discovery in any particular part of the subject, but of a general and considerable advance in all departments. There was first of all a much quickened interest in the subject of plant diseases on the part of the departments of agriculture in all the more progressive countries of the world. More funds became available for the investigation of disease problems, and the number of workers in this branch of botanical science correspondingly increased. (See also BOTANY; ECOLOGY.)

In this respect the United States of America, with its varied and as yet somewhat experimental system of agriculture, still occupies the leading place, but Britain is following in the same direction, especially in connection with the development of her tropical colonies and dependencies. As a consequence of this increased activity, the period under consideration produced a vast accumulation of scientific literature; many diseases new to science and of greater or less importance have been described; more detailed knowledge on the subject of the older and better known diseases has been obtained; and as regards the purely practical aspect of the problem improved methods of dealing with plant diseases have been developed. The latter include more efficient methods of spraying, dusting, etc., for the purpose of checking the onset of disease, and, what is of perhaps greater economic importance, the breeding of varieties of economic plants which are immune or at least resistant to certain diseases.

**Virus Diseases.**—What are now known as the “virus” diseases of plants were formerly considered as physiological diseases, i.e., as being due to certain disturbances of function not correlated with the presence of a parasite. The recognition of their infectious or contagious nature, either by direct inoculation or by grafting, was a great step in advance. The general view now held is that they are due to a “virus” which is ultra-microscopic and which will pass through the pores of certain filters. As to the nature of the virus, whether it is a kind of very small bacterium, or an enzyme, or an organism *sui generis* (Twort), no definite decision can at present be given. (See FILTER-PASSING MICROBES.)

A large and ever increasing number of economic plants prove to be susceptible to diseases of the virus type. To mention some of the better known: the various forms of virus disease of the potato (mosaic, leaf-roll, crinkle, etc.), the mosaic diseases of tomato, tobacco, cucumber, hops, sugar-cane, various beans, clover, raspberry, dahlia, etc.; the “curly top” disease of sugar beet, a number of peach diseases and the phenomenon known as “infectious chlorosis.” To the same category probably belong the well-known “reversion” of black currants which is troublesome in England, and the “spike disease” of sandalwood in South India.

In Britain the most important virus diseases from the economic point of view are those occurring on the potato. These are widespread, especially in the warmer and drier parts of the country. Researches have shown that virus disease is the chief cause of the deterioration, i.e., of the loss of cropping power which potato stocks suffer in the warmer parts of Britain. The view held formerly was that this deterioration was due to climate *per se*, the potato being considered to be a plant of cold climates and therefore not maturing its “seed” properly under warmer conditions. According to the latter view, deterioration is thus inevitable, the only way to keep up the cropping power of the potato being to import more vigorous “seed” from farther north. Those who hold the “virus” theory, on the other hand, point out that the effect of climate is only indirect, in that it encourages the multiplication of insects (aphides) which are

the natural agents for spreading the disease in the field. Prevention of deterioration is thus possible, either by control of the insects concerned, or, failing that, by the provision of disease-free stock in the first instance and avoidance of subsequent contamination. The prompt recognition of diseased plants and their removal ("rogueing") before the disease has been carried to neighbouring plants is the practical method of controlling virus diseases of the potato and virus disease in general.

**Carriers.**—Apart from their economic importance, great scientific interest attaches to diseases of the virus type. The nature of the active principle has been the subject of numerous researches (Allard, Doolittle and others). There exist definite "carriers" of the disease—that is, plants which on inoculation show no symptoms of disease in themselves, but are able to transmit the disease to susceptible plants. This feature affords an interesting parallel to what is met with in certain animal diseases, e.g., typhoid fever. In fact, the virus diseases of plants are in general very similar to the corresponding diseases in animals, and serve as a kind of common ground for the sciences of plant and animal pathology—two sciences which in the main are very different.

**Diseases Due to Fungi.**—As regards plant diseases of a purely fungoid type, the expansion of world agriculture, and especially the agricultural development of the tropics, proceeds apace, and thus economic crops are brought into contact with new environments where they are liable to attack by parasites unknown in their old habitat. Furthermore, the plantation method of cultivating tropical tree crops as opposed to the sporadic occurrence of these plants under natural conditions brings with it greater dangers from parasites, as the mass formation of a plantation lends itself readily to the spread of disease once the latter has entered. New fields of investigation are thus constantly being opened up. Even in countries with a stable and long-established system of agriculture such as England, new problems may suddenly arise, as witness the wart disease of potato (*Synchytrium endobioticum*). In the early years of the century this disease was almost unknown, but in the period under consideration it attained serious dimensions, so much so that its presence determined the whole development of the potato industry in England in later years.

Among diseases which have become of considerable importance in England mention may be made of the silver leaf disease (*Stereum purpureum*) of plums and other fruit trees; the American gooseberry mildew (*Sphaerotheca mors-uvae*), which is firmly established and the downy mildew (*Pseudoperonospora humuli*), which is a constant source of danger to hop cultivation. In the United States the bark disease (*Endothia parasitica*) of sweet chestnut, which came in from Japan, and the white pine blister rust (*Chromartium ribicola*), which is native to Europe, have caused great damage. The problems of rusts and smuts in cereals have received a large amount of attention in all grain-growing countries; and the same may be said of a number of fungi which cause foot-rot, leaf stripe or barrenness of ears in various grasses (*Ophiobolus*, *Helminthosporium*, *Gibberella*).

In various countries a whole group of "wilt" diseases, due chiefly to a species of *Fusarium*, has come into prominence—wilt of cotton, of banana, of various leguminous and solanaceous plants, etc. Some of these, e.g., the cotton wilt, have been definitely controlled. Banana wilt, on the other hand, is not yet under control, and this fact is of the utmost importance in the banana industry. The establishment of the rubber industry in the East brought in its train a whole literature of fungoid diseases (*Pomes*, *Corticium*), as well as the somewhat obscure brown bast disease. The rubber plantations in the East have not as yet suffered from a leaf spot disease (*Melanopsammopsis*), which has so far prevented the establishment of rubber plantations on the South American continent, the natural home of the *Hevea* rubber tree. An interesting internal boll-disease (*Nematospora*) has been described from the West Indies. In this case the active transmitting agents are biting insects. From present indications it is not unlikely that this disease will prove to be an obstacle in the way of cotton cultivation in parts of Africa.

**Diseases Due to Bacteria.**—Bacterial diseases of plants, which were at one time believed to be non-existent, are now known to be fairly common, and some have proved to be of great economic importance—for example, the angular leaf spot disease (*Bacterium malvacearum*) of cotton, which is especially severe on Sea Island and Egyptian types; the citrus canker (*Pseudomonas citri*), which has caused great damage in Florida, South Africa, etc.; the pear blight (*Bacillus amylovorus*), which is serious in various parts of Canada and the United States; and the wild fire disease of tobacco (*Bacterium tabacum*), which is now one of the most important diseases of tobacco in the United States and South Africa. The crown gall organism (*B. tumefaciens*) has been much studied with special reference to its supposed resemblance to human cancer, but this analogy has been called in question. (See BACTERIOLOGY.)

**Breeding of Immune or Resistant Varieties.**—With regard to methods of prevention or treatment of plant diseases, the period under consideration shows considerable advances. Much is now known on the subject of the inheritance of immunity or susceptibility to plant disease, and as the practical result of breeding work varieties immune or highly resistant to disease have been developed. In England many high-class varieties of potato have been developed which are entirely immune to wart-disease. Wheats highly resistant to rust (and with other good commercial qualities) have been established (Biffen, Nilsson-Ehle), varieties of hops immune to mildew (Salmon), of asparagus resistant to rust (Norton), of beans resistant to anthracnose (Barrus, Burkholder), and so on. By simple selection of resistant individuals in the field, strains of cotton and cowpea have been isolated which are highly resistant to wilt (Orton, Watson). Similar success has been obtained in the same way with the tobacco root rot (Garner).

**Strains of Parasitic Fungi.**—The problem of breeding immune or resistant varieties has been complicated by the discovery that many parasitic fungi exist in a number (sometimes a large number) of "biologic forms" or races, each of which has a different host range. Hence a plant which is immune in one area may be susceptible in another, the strain of the parasite being different in the two areas. This feature of parasitism, which has been made out in very striking form in connection with the black-stem rust of cereals (Stakman and co-workers), leads to the practical conclusion that breeding for disease resistance must be a regional problem. The first step in the solution of the problem must be the determination of the strain of fungus prevalent in the given area, and hence the value of the plant disease surveys which have been taken up by the agricultural departments of various countries. Stakman's work, however, while indicating unexpected difficulties in the way of obtaining immune varieties, has led to a simplification in another direction. The old view of a "bridging species," according to which a fungus is able to pass from a susceptible plant to one which is otherwise immune (Ward, Salmon, Pole-Evans), has been considerably discredited, so that there are now strong grounds for thinking that once an immune variety has been obtained it will remain so as long as it does not come into contact with a fungus of different parasitic power.

**Prevention by Sprays, etc.**—Many advances in detail with regard to the chemical control of disease by the use of sprays and washes have been made. These have been made possible to a large extent by the increased knowledge of the life-history of the various pests, so that more exact information with regard to the best time for spraying can now be given. This item makes all the difference between success and failure in spraying. The technique of preparing spray fluids has received much attention, with a view to obtaining the maximum fungicidal efficiency with the least damage to the plant. Improvements have taken the form of presenting the active chemical in a finer state of division, in the perfecting of spreading reagents (soap, casein preparations) and in the use of new fungicidal chemicals, such as "Uspulum." Dusting has been much advocated in place of spraying as being more practicable, and in many cases as being equally effective. The latest development along these lines is

the use of aeroplanes for dusting, as in the campaign against the cotton boll weevil in the southern United States. (See COTTON.) The same methods may be applied to rust control in wheat-growing regions.

**Control by Eradication.**—The control of certain diseases in which the parasite passes a part of its life-history on an alternate host is illustrated by the "Barberry Eradication" campaign in the northern part of the wheat belt in the United States and Canada, the barberry being the alternate host of the black stem-rust of wheat. A similar campaign to eradicate species of ribes, which are alternate hosts to the rust of the Weymouth pine, is in progress in the eastern United States. The control of internal boll disease of cotton in the West Indies by the cutting down of certain Malvaceous trees, on which the transmitting-insects lived during the period when the cotton was not on the land, is a striking example of the same method.

**Biological Methods of Control.**—A method of control which refers particularly to diseases of insect origin is the introduction and acclimatisation of enemies (parasites or "predators") of the injurious insect. It frequently happens that in trying to establish a new crop in a country some insect pest by-and-by gets in, and that the latter in the absence of its natural enemies flourishes exceedingly and becomes a serious menace to the crop. By investigations in the original home of the crop it has been found possible in many cases to determine the natural enemies of the insect pest, either parasitic or predatory insects, or in a few cases bacteria or fungi, and to establish these in the new country. Many of these efforts have resulted in failure, due to faulty methods of procedure or to the intrinsic difficulty of the problem. In some cases, however, brilliant success has been achieved, as in the control of the sugar-cane leaf hopper in Hawaii. Strenuous attempts are made by the United States Department of Agriculture to control the ravages of the corn borer insect by the introduction of its natural enemies in Europe, its original home. Research along these lines appears to be one of the most promising outlets for entomological science for the future.

**Legislation.**—A marked feature in recent years is the increasing amount of governmental control which is coming into being in connection with plant diseases. This development is to a certain extent the outcome of the increased transportation of plant products incidental to commerce generally and to the establishment of new crops in new countries. Control methods are in many cases useless unless carried out thoroughly and simultaneously and in a specified manner over the whole area concerned. As between nations governmental control takes the form of inspection at the port of entry, of quarantine and in certain cases of actual exclusion. Thus the import of gooseberry stock into England from the United States is forbidden on account of the mildew, and conversely the import of English potatoes into the United States is forbidden on account of wart disease. Considerable controversy has arisen as to the efficacy of these measures, as in many cases they are applied too late. Irritation is also caused by the fact that, while such regulations were primarily intended for the express purpose of excluding certain pests, they are capable of being used for the furtherance of economic profit.

Governmental control within the limits of any particular country takes the form of compulsory notification of certain diseases; of the prohibition of growing particular varieties in certain "scheduled" areas, of the inspection and certification of seed and stock plants and of the enforced clearing up of plant material which constitutes a source of danger to succeeding crops. The control of wart disease and of silver leaf disease in England is a good illustration of these methods, and in the former case at any rate very considerable success has been achieved. An interesting experiment along the same lines is in progress in British West Africa, where a universal clearing up of cocoa diseases is being attempted.

**Scientific Developments.**—Developments in the more scientific aspects of plant pathology have dealt mainly with the physiological study of the interrelation between host and parasite and

with the effect of external factors on the incidence of parasitism. In the latter connection temperature and humidity have received most attention, e.g., the relation between parasitic attack and soil temperature (Jones and co-workers), and the effect of low temperatures on fungal growth and parasitism (Brooks, Cooley). These investigations have a practical outlook, especially with regard to the transportation and cold storage of fruit, a subject to which great attention is paid (Stevens, Hawkins, Kidd, West). Another direction in which advance has taken place is the discovery of "saltation" or mutation in fungal organisms (Crabill, Stevens, Brown and others). The occurrence of this phenomenon has probably a direct bearing on the existence of the many strains of pathogenic organisms already alluded to.

**PLANT PHYSIOLOGY** (see 21.744).—This branch of botany has made such great advances and it touches physics and chemistry so closely that it has almost become a separate subject. Progress has been made over such a wide field that only a few important developments are referred to.

**Photoperiodism.**—It is a familiar fact that, at least in temperate climates, many plants flower at certain periods of the year only. There are so-called spring flowers, autumn flowers and plants which flower in the summer. This marked seasonal effect must be due to some varying external condition or set of conditions. It has often been supposed that temperature plays a large part in the development of flowers, and a certain degree of warmth is essential for growth, yet altering the temperature alone will not markedly alter a plant's flowering period. Asters and chrysanthemums cannot be made to flower in summer by lowering the temperature nor irises in winter by putting them in a greenhouse. Apart from temperature there is one regular cyclical change associated with the march of the seasons and that is the change in the length of the day and night, the day in the latitude of London varying from 16½ hours in June to a little under eight hours in December.

It has been shown by Garner and Allard (1) that in the case of many plants it is the length of the day which is the decisive factor in fixing the season of flowering. The discovery was made in the United States, where the behaviour of a valuable variety of tobacco known as *Maryland Mammoth* was being studied. It had been found impossible to obtain seeds from this variety since it went on growing steadily through the season, sometimes reaching a height of 12 ft., being eventually cut down by frost before it had formed flowers. One autumn a specimen was transplanted to a greenhouse, where it promptly flowered and set seed. This was at first thought to be an effect of temperature, but further investigation showed that it was impossible to cause the plants to flower in the summer. It was soon found that the dominating factor was length of day; if growth conditions were favourable it would flower in the short days of late autumn or winter but not in the long days of summer. By artificially shortening the day to 12 hours by placing the *Maryland Mammoth* plants in the dark during some of the daylight hours, flowering could be brought about at any time of the year.

Following up this discovery of the behaviour of the variety of tobacco, Garner and Allard investigated at Washington the behaviour of a large number of plants. These were grown in pots which were borne upon light trucks running on tram-lines so that the pots could be run in and out of sheds and thus be illuminated for various fractions of the daylight period. Many plants, such as the tobacco variety mentioned above, soya beans, asters, chrysanthemums, poinsettia, were found to be "short day" plants, and would only flower when the period of daylight was reduced to 12 hours or less. If the time of illumination is suit-

ably adjusted the plants will flower and fruit when they are quite diminutive, while other individuals exposed to full daylight grow to a large size without any trace of flower production. Other plants such as grasses have been shown to be "long day" plants which require a long daily period of illumination for the initiation of flowering (2).

**Phototropism.**—In the physiological field of irritability of plants the question which has perhaps been most discussed of recent years has been that of the nature of the response of plant organs to light from one side. It is known that many stems when exposed to unilateral light grow toward the light. The earliest view was that this reaction was a response to the greater intensity of illumination on the near side as compared with that on the far side. When, however, it was found that many transparent organs such as root hairs and fungal hyphae would respond to light, the view that the plant organ was sensitive to the direction of the incident light came to the front. Blaauw (3) was the first to put forward against this view a simple theory of the phototropic response. He showed that simple unicellular structures like the sporangiophore of *Phycomyces* and the hypocotyl of *Helianthus* exhibited a very definite "light-growth reaction" when illuminated all round, the rate of growth being increased in *Phycomyces* and reduced in *Helianthus*. Light, apart from direction, has thus an acceleration effect in the one case and an inhibiting effect in the other. The turning of the hypocotyl of the sunflower toward the light is explained by the relatively greater retardation of growth on the side turned toward the light. It would seem that the sporangiophore of *Phycomyces* should turn away from the light, but it was shown that this glass-like cylindrical structure acts as a lens, the light being focussed on the further side which is thus the more intensely illuminated of the two.

Later, it was shown by Buder (4) that if the sporangiophore is placed in liquid paraffin and exposed to unilateral light the focussing effect is no longer produced, and the nearer side is the more highly illuminated, with the result that the organ now grows away from the light. As a result of his work Blaauw put forward the view that phototropism is simply a growth response to the different intensities of illumination of the two sides of the plant organ. The light probably acts in some photochemical way and this affects the cell processes. Buder's (5) experiment, in which one half of the coleoptile of the oat was illuminated by a pencil of light coming directly from above; and also that in which the hollow coleoptile was illuminated on one side by a pencil of rays coming from the inside outwards, speak strongly in favour of the theory that the response of orthotropic organs is to differences of light intensity and not to light direction.

**Conduction of the Phototropic and the Geotropic Stimulus.**—Interesting results have recently been obtained by studies on the conduction of the phototropic and geotropic stimulus. If the apex only of the coleoptile of oat be illuminated, the stimulus is conducted to the lower part which becomes curved. It was first shown by Boyson-Jensen, and later more fully by Pál and by Stark, that if the tip is cut off and stuck on again by means of a thin film of gelatine, illumination of the tip while the lower part is kept darkened will still bring about curvature. The conduction takes place through the layer of gelatine, and it will also pass through a thin sheet of cane covered with gelatine; but if a thin sheet of mica or of metal be used there is no transmission of the stimulus. This indicates that the agent responsible for the conduction is some diffusible material and not an electric current. It has also been shown by Snow (6) that a similar phenomenon is to be observed in connection with the geotropic stimulus. He finds that if the primary roots of the broad bean (*Vicia Foba*) are decapitated and the tips are stuck on again with a film of gelatine the roots become again capable of curving under the action of gravity. The conduction in this case also appears to be due to the diffusion of some soluble substance. The diffusion from the tip of a substance important in growth reactions is not confined to organs which are phototropically and geotropically stimulated. If the tip of a coleoptile kept vertical is removed the rate of growth of the coleoptile is slowed down but the replace-

ment of the tip increases again the rate. A growth promoting substance seems thus to be continually passing downwards from the apex.

**Permeability.**—There have been many investigations dealing with the permeability of the plant cell but the nature of the plasma membrane, which largely controls the entry of substances, and the forces which lead to the accumulation of substances in the cell are still very obscure. The whole subject has been reviewed by Stiles (7). A clearer picture, however, has now been obtained of the water relations of the cell. The plant cell usually exhibits an osmotic pressure which ranges from about 11 to 40 atmospheres and may reach over 150 atmospheres. In addition to this outwardly directed osmotic pressure (P) there is in turgid or partially turgid cells an inwardly directed pressure, the wall pressure (T). In a fully turgid cell, *i.e.*, one which is fully imbibed with water, the wall pressure is equal to the osmotic pressure, *i.e.*,  $P = T$ . In a partially turgid cell the wall pressure is less than the osmotic pressure: the difference ( $P - T$ ) between these two pressures is the suction pressure (S). If the cell is lying in water this suction pressure is a measure of the pressure forcing water into the cell. The "water absorbing power" of a cell, as it used to be called, is thus determined not by the osmotic pressure of the cell but by its suction pressure. Whether one cell will absorb water from another depends not on their relative osmotic pressures but on their relative suction pressures; a slightly turgid cell with a low osmotic pressure can take water from a fully turgid cell of much higher osmotic pressure. When the cell is plasmolysed the suction pressure is at its highest, and is equal to the osmotic pressure of the cell sap; when the cell is fully turgid the suction pressure is zero.

**Respiration.**—The work of Neuberg and his collaborators (8) has placed our knowledge of the chemistry of the related process of alcoholic fermentation on a firm basis. The probability is very great that pyruvic acid is an intermediate product in the conversion of a hexose sugar into alcohol and carbon dioxide. Normal respiration follows rather different lines; in essentials it is the exact opposite to photosynthesis (carbon assimilation). In that process sugar is built up from water and carbon dioxide with the aid of the energy of light. In respiration, sugar is oxidised to carbon dioxide and water with the liberation of heat. It may be represented thus:—

$C_6H_{12}O_6 + 6O_2 = 6H_2O + 6CO_2 + 674,800 \text{ calories.}$  Other substances may be oxidised in the process of respiration but sugar appears to be commonly used. There are various theories as to the mechanism of respiration, one being that oxidation is due to a peroxide and an enzyme (peroxidase). Such oxidising enzymes, although they will oxidise a number of aromatic substances present in the plant, will not act on the materials such as sugars which are used in respiration. Of late years the view of Wieland has been very much to the fore. In this view the process of physiological oxidation is really a process of combination with water, followed later (probably under the action of an enzyme) by a process of *dehydrogenation* in which hydrogen is split off, the material being finally reduced to carbon dioxide. The hydrogen formed, which is in an active state, combines with the oxygen in the air to form water. Wieland has shown that, in the absence of oxygen, respiratory material such as glucose can produce carbon dioxide at ordinary temperatures when in the presence of water and some catalyst (such as palladium black) provided that some "acceptor," as it is called, of hydrogen is available. Methylene blue or hydroquinone can act as such an acceptor. In the view of Warburg (9) the process of respiration is essentially a *surface* reaction. It has been shown that if blood corpuscles be reduced to an emulsion by freezing and thawing, respiration will go on, but it is confined to the solid portions of the emulsion, *i.e.*, to the cell fragments. The same applies to broken-up egg cells. Warburg has shown that various substances, such as oxalic acid, amino acids (leucin and cystine) and even sugars, when adsorbed on the surface of animal charcoal, are oxidised with considerable rapidity. As a result of these oxidations the same substances are produced as arise when these materials are respired in the living organism.

This view of oxidation at a surface receives support from the fact that narcotics not only retard the process of respiration but also the oxidation of substances by animal charcoal. Furthermore, the narcotics are the more effective the greater their degree of adsorption by the charcoal; by their active adsorption they displace the material from the surface. It is found that hydrogen cyanide (HCN) has a far greater effect in solution than can be explained by its adsorption. Warburg is thus led to the view that iron plays a very important part in the process, the oxidation only occurring on those parts of the surface (of the charcoal or the cell) in which iron is present. The hydrogen cyanide is peculiarly active because it alters the iron chemically so that it is no longer active as a catalyst. In Nathansohn's (10) view the physiological oxidations characteristic of respiration are essentially electro-chemical. Small membrane potentials in the cells may lead to the electrolytic dissociation of water, the nascent hydrogen being removed by the same "acceptor" and the active oxygen bringing about the oxidation of respiratory materials.

**PLATA, RIO DE LA**, or **RIVER PLATE** (see 21.786), the great estuary on the east side of South America, between the republics of Argentina and Uruguay, into which flow the rivers Paraná and Uruguay with their tributaries. During the 20 years ending in 1926 many of the ports, cities and towns located on the Plata-Paraná-Paraguay river system have made marked progress. Millions of dollars have been spent in extending and improving shipping facilities by Montevideo, La Plata, Buenos Aires, Rosario—all of them ports of call for ocean-going steamships. Many of the smaller ports like Santa Fé, Paraná, Corrientes, Posados and Asunción, have also improved their facilities, and have increased their exports of grain, hides, meat, quebracho wood and extract, maté and lumber. A decided impetus has been given to river shipments by the development in the lumber and cattle and meat canning industries, following on the purchase by North American interests, in 1915-6, of nearly 2,000,000 ac. of land, several hundred miles north of Asunción, Paraguay.

**Communications.**—The completion, in 1916, of a 37 m. railway around the Falls of Guayra, on the Alto Paraná river, opened a new river and rail gateway to the heart of Brazil, the principal outward shipments being yerba-maté and dried beef. A new hotel at Iguazu River Falls and a motor-car service from Puerto Aguirre to the Falls, 10 m. distant, provide modern accommodation, and, aided by better steamboat service on the Alto Paraná have brought more tourists to the cataracts. The Rondon, the Roosevelt (1913-4) and other expeditions of recent years; the colonisation schemes of European and American companies in Paraguay and Bolivia; the completion of a Brazilian railway from São Paulo nearly to the Paraguay; petroleum investigations in eastern Bolivia; larger areas planted with cotton in Argentina and Paraguay have combined to arouse wider interest in the vast region watered by the Plata river system. On the Uruguay river the cities of Mercedes, Paysandú and Salta have new water systems, improved streets and extended sanitation. A packing plant at Fray Bentos has increased operations there. The Argentine Navigation Co., the Lloyd Brasileiro and local steamboat lines

operate La Plata services to Corumbá, Brazil, 1,800 m. from the Atlantic. Deep-draft vessels ascend as far as Rosario, 200 m. above Buenos Aires. Throughout the Plata region the gradual introduction of modern agricultural implements has increased output, and, consequently, river traffic.

**PLATT, CHARLES ADAMS** (1861— ), American architect and sculptor, was born in New York City Oct. 16 1861. His education in art was acquired in the National Academy of Design, New York City, after which he went to Paris in 1882 and studied under Boulanger and Lefebvre, returning to the United States in 1887. His intention had been to become a painter and etcher, but the outcome of a visit to Italy was a book, *Italian Gardens* (1892), which showed that he had been captivated by the architectural spirit of the Italian Renaissance. As a consequence he turned to architecture, in which his work showed the marked influence of Italian form. He designed a large number of private houses and gardens in addition to public buildings, among the latter being the Maxwell Memorial Library, Rockville, Conn. (1917); The Freer Gallery of Art, Washington, D.C. (1918); the Library, Connecticut College for Women, New London (1922); the Agricultural building, University of Illinois, Urbana, Ill. (1923); and the Lowell Memorial Fountain, New York City. See *Monograph of the Work of Charles A. Platt*, with an introduction by Royal Cortissoz (1913).

**PLAYER PIANO:** see **MUSICAL INSTRUMENTS**.

**PLAYFAIR, NIGEL** (1874— ), British actor and theatrical manager, was born in London July 1 1874. Educated at Harrow and at University College, Oxford, it was at Oxford that he gained his first theatrical experience with the Oxford-University Dramatic Society and other amateur acting societies. For some time he practised as a barrister, and it was not until July 30 1902 that he made his first appearance as a professional actor at the Garrick Theatre, London, in "A Pair of Knickerbockers." He afterwards played many other parts, but was chiefly associated with the Lyric Theatre, Hammersmith, London, the management of which he assumed in 1919. Among his most famous productions at this theatre were John Drinkwater's *Abraham Lincoln* (1919) and the revival of Gay's *Beggar's Opera* (1920) which ran for over three years. He published a number of volumes, including *The Story of the Lyric Theatre, Hammersmith* (1925), and contributed verses to London periodicals.

**PLEBISCITE** (see 21.834), politically a method of ascertaining the general desire of the inhabitants of a given territory or area. As a means of settling the destination of populations and territories the method of the plebiscite is comparatively new. It was first used in the French Revolution to defend the wholesale annexations of territory made by the conquering French Republic, and subsequently by Napoleon I. It was revived by Napoleon III. and applied (successfully for him) in the case of Nice and Savoy, and (successfully for Victor Emmanuel) in the duchies of north Italy during the years 1859-60. These cases were comparatively simple, for the area in each instance was historic and defined and the question was—Did such area want to remain as it was or become absorbed in a larger unit?

The Peace Conference of 1919 decreed plebiscites without much discrimination, in cases where it seemed desirable to soften the blow to a defeated enemy or to get over a difficult diplomatic crisis. They were not generally conceded as a matter of principle, but resorted to as an expedient.

**Plebiscites After the War.**—In connection with the Peace Conference of 1919 17 plebiscites were proposed, and of these only eight were actually held. Of these the Turkish plebiscite in Transcaucasia was a farce. Those of Allenstein Marienwerder (q.v.) retroceded territory disputed between the Germans and Poles to the former. That of Oedenburg returned part of west Hungary from Austria to Hungary (see **BURGENLAND**). That of Klagenfurt (see **AUSTRIA**) returned the whole Klagenfurt basin (which was claimed by the Yugoslavs) to Austria. None of

these five was of great importance, but the remaining three did decide questions which could not have been equally settled by other means. Two plebiscites were held in Luxembourg. The first, a political one held after the deposition of the Grand Duchess, elected her younger sister in her place by a great majority. The second, an economic plebiscite, decided by a large majority for an economic union not with Luxembourg's neighbour Belgium, but with France. But these, though held under the influence of were not actually directed by the principal Allies.

Solid and permanent results, like those obtained in Luxembourg, were likewise reached in Schleswig (*q.v.*). Bismarck had given a promise in 1866 to take a plebiscite in the northern or Danish area of this territory which he had not carried out. The Peace Conference of 1919 put into practice this project by a plebiscite which was a model of fairness. The net result was to cede the southern or Flensburg zone to Germany and the northern area to Denmark, a division satisfactory on every ground and giving indications of permanence.

The plebiscite in Upper Silesia (*see* SILESIA) was the most gravely contested of all such popular votes. Intimidation by Polish volunteers under Korfanty and the hardly disguised Polish sympathy of General La Rond, the French president of the plebiscite commission, caused much difficulty. Finally, after the vote had been taken, arrangements for partitioning the territory between Poland and Germany were sharply contested between Great Britain and France. It was finally settled in Oct. 1921 by an appeal to the League, which laid down a frontier considered by independent critics as unduly favourable to Polish claims.

The net result of the Peace Conference was to discredit rather than to advance the method of decision by plebiscite. Much clearly depends on the method of taking a plebiscite or the previous condition of the country, and on the size of the electoral areas in which the vote is taken. And it is plain that these difficulties were not successfully surmounted in most of the plebiscites taken at the bidding of the Peace Conference at Paris in 1919.

**PLEKHANOV, GEORGY VALENTINOVICH** (1857–1918), Russian Socialist, was born Nov. 26 1857 in the province of Tambov, of an old noble family. His father wished him to enter the army, but while a student he joined the Narodnist (populist) revolutionary movement. At the age of 20 he led the first great popular demonstration at St. Petersburg (Leningrad) in the Kazansky square (Dec. 18 1876). When the Majority section of the Narodniks adopted terrorist methods in 1879, Plekhanov seceded, and later with Deutsch, Axelrod and Vera Sassulich, created the Marxian Russian Social Democrat party (1884). He spent 40 years in exile, chiefly at Geneva and later at San Remo. He was associated with Jules Guesde, Liebknecht and Clara Zetkin (who translated his book on Tchernichevsky), was Russian delegate to the Socialist International congresses held in Paris (1889) and in Copenhagen (1910). He was the recognised leader and philosophic exponent of Russian Marxism, his most famous book being *The Materialistic Conception of History*, and wrote also a remarkable booklet directed against anarchism.

Up to the split between the Bolsheviks, or Left Wing, led by Lenin, and the Mensheviks, or Right Wing, led by Martov, in 1907 he was the leader of the Social Democrat party. At first neutral in his attitude, desirous of re-establishing unity, he became a strong opponent of Lenin's "anarcho-syndicalism" and of his conception of the dictatorship of the proletariat. In the World War Plekhanov advocated resistance of German militarism and attacked Lenin's extreme anti-war tactics. When the Russian revolution came, he returned to Russia in spite of illness and was triumphantly received at Petrograd (Leningrad) (March 31 1917), and was invited to join Kerensky's Government. He refused, but supported Kerensky against the

Bolsheviks in the bitter Press campaign which followed, and was brutally handled by riotous Red Guards during the Bolshevik revolution (Nov. 1917). He died in Finland May 30 1918. The Soviet Govt. has erected several statues to his memory and published an official edition of his works.

**PLENER, ERNST, FREIHERR VON** (1841–1923), Austrian politician, was born on Oct. 18 1841 at Cheb in Bohemia, the son of the Austrian statesman Ignaz von Plener (1810–1908). He began his diplomatic career in 1865, and served in the Paris and London embassies until 1873. In the latter year he was elected by the chamber of commerce of his native place to the Chamber of Deputies of the Reichsrat, where he was soon reckoned among the most conspicuous members of the constitutional party. In the Taaffe period (1870–93) he was one of the leaders, and from 1888 the acknowledged head of the German-Liberals in their struggles against the Slav-Conservative majority in the Chamber. Consequently he represented Germanism on the nationalities question, but was not averse to concessions compatible with the maintenance throughout the whole monarchy of the position due to the German Austrians. He sought to compromise the quarrel between Germans and Czechs, and the so-called "points" of 1890, a summary of the bases for a German-Czech understanding, were essentially his work. In the Windischgrätz Coalition Ministry (1893–5), Plener took over the portfolio of Finance. Soon after his retirement from the Finance Ministry, Plener was appointed president of the Supreme Audit Department (*Oberster Rechnungshof*). He became a member of the Upper House in 1900, and died May 1 1923 in Vienna.

Plener wrote a series of economic and political works, among others *Die Englische Fabriksgesetzgebung* (1871); *Englische Baugenossenschaften* (1873). His speeches were published by his friends in 1911. He himself published *Erinnerungen*, 3 vol. (1911–21).

**PLIEKŠANS, JĀN** (1865– ), Latvian poet and dramatist, was born Sept. 12 1865 at Tadenava in the district of Ilukst, Courland. He adopted the pen name of Jozsef Rajnis. He was educated at the Riga gymnasium, and from 1884 to 1888 studied law at St. Petersburg (Leningrad). He later practised as a barrister at Mitau, Courland. From 1891 to 1895 he edited in Riga a democratic Latvian paper, *Dienas Lapa* (Daily Paper). He was arrested by the Russian Govt. on political grounds and deported first to Pskov and then to Viatka returning thence in 1903. He may be considered the chief exponent of democracy in Latvian poetry. He invented a special form of sonnet, shorter than the ordinary sonnet and well constructed. As a dramatist he achieved distinction, not only as a translator of Shakespeare, Goethe and Schiller, but also by his own tragedies written in the Lettish language. His principal historical tragedies are *Uguns un nakts* (*Fire and night*), *Pūt vējini* (*Blow breeze*) and *Daugava* (*The Dvina*). *The Sons of Jacob* has been translated into English, and was produced May 22 1925, at the New Scala Theatre, London, by the International Theatre Society. For several years he was director of the Latvian National Theatre, and in 1920 became a member of the Latvian Saeima (parliament).

**PLOUGH:** *see* TRACTOR.

**PLUMER, HERBERT CHARLES ONSLOW PLUMER, 1ST BARON** (1857– ), British soldier, was born March 13 1857, and entered the army in 1876. He served on the Red Sea littoral in 1884, and in 1896 commanded a mounted regiment in the Matabel Campaign. Before the outbreak of the South African War in 1899 he raised the Rhodesian field force, which he commanded during the early months of the contest. He was promoted major-general on the conclusion of hostilities.

In May 1915 Sir Herbert Plumer was selected to lead the II. Army on the Western Front. His army was not very actively engaged during the remainder of 1915, nor yet in 1916, but on June 7 1917 Plumer gained a signal victory at Messines. (*See* YPRES, THIRD BATTLE OF.) In Nov. he was selected to take charge of the British troops that were being sent to the basin of the Po after the Italian defeat at Caporetto. He commanded them until March but he was then summoned back to

Flanders to resume the leadership of the II. Army just before the great German offensive started. When the general advance of the Allies began in August, his army took a prominent part in the operations by which Belgian Flanders was recovered from the invaders. For his services in the War he was raised to the peerage as Baron Plumer of Messines and of Bilton, was promoted field marshal, and received a grant of £30,000. He subsequently commanded the British forces on the Rhine for a short time. From 1919 to 1925 he was governor of Malta and in 1925 became high commissioner for Palestine.

**PLUNKETT, SIR HORACE CURZON** (1854– ), Irish politician (*see* 21.857), after his retirement in 1907 from the vice-presidency of the Irish Agricultural Department took no prominent part in politics till the crucial year, 1914. In the spring of that year he made abortive suggestions for an agreed settlement of the Irish question; and then in July, just before the outbreak of the World War, he announced his conversion to Home Rule and appealed to Ulster to give Home Rule a chance. In 1917, a year after the Dublin rebellion, he took the lead in a further attempt at a solution of the problem. When Mr. Lloyd George set up a comprehensive convention of Irishmen to consider the matter, there was great difficulty in finding a suitable chairman; but the first meeting unanimously chose Sir Horace for the post. He was himself sanguine, and worked at his task with singular devotion; but the absence of Sinn Féin from the gathering, the impossibility of reconciling the views of the Ulstermen and those of the Southern Unionists, and the occurrence of a number of tragic events in Ireland, prevented the adoption of any report with colourable unanimity. In 1920–1 he was a prominent advocate of "Dominion Home Rule," and saw it adopted in the Irish Treaty. He served as a Senator of the Irish Free State in 1922–3. (*See* IRELAND: *Agriculture*.)

**PLYMOUTH**, England (*see* 21.861), which has included Devonport and Stonehouse since 1914, had a population in 1921 of 209,857 and an area of 5,711 ac. in the borough. Morice Town, to the north of Devonport and Stoke, is a rapidly growing district. Plymouth has returned three members to Parliament, from the Drake, Devonport and Sutton divisions, since 1918. Lady Astor, the first woman to sit in the House of Commons, was returned in 1919. By the municipal reorganisation of 1914 the town was divided into 14 wards, and has now a mayor, 20 aldermen and 60 councillors. The municipal museum and art gallery were finished in 1910, and a free library has been opened in Tavistock Road. The church of St. Gabriel, Compton Gifford, was built and made into a parish in 1910, and that of St. Boniface, St. Budeaux, was built in 1913, and made a parish in 1916. A parish was formed from that of Sutton-on-Plym in 1911. A memorial to men of the Royal Marine Light Infantry was unveiled on the Hoe in 1924, a naval memorial in 1924, and one to Capt. Scott and his comrades in 1925. Milbay Pier in the harbour has been extended to give further accommodation for mail steamers.

**PNEUMONIA:** *see* RESPIRATORY SYSTEM, DISEASES OF THE.

**PNEUMOTHORAX.**—The lungs are elastic organs kept in a condition of extension by their attachment to the walls of the bony thorax. This attachment is not direct, but is effected through the intervention of a smooth-walled empty sac, the pleura, which on the one hand covers the lung, and on the other forms a lining to the thoracic wall. The surfaces of this sac are held in contact by the weight of the atmosphere, and glide over one another during movements of respiration. If gas or air gain entry, whether from without or within, the lung is released from its condition of extension, and on account of its elasticity tends to collapse and empty itself of air. This is the condition known as Pneumothorax, and according to the means of its production is spoken of as Spontaneous or Artificial.

*Spontaneous Pneumothorax.*—This is generally due to the rupture of an air-containing lung into the pleural sac, commonly caused by softening of a tuberculous nodule. According to the size and nature of the rupture the pneumothorax is formed gradually, with slow development of symptoms or suddenly with immediate and urgent distress. A rapid and complete collapse of one lung, accompanied, as commonly happens, by en-

croachment of the chest contents on the other lung, is a condition that leads to severe breathlessness. Where, however, the collapsed organ was extensively diseased its loss may be less urgently felt and occasionally its collapse may be actually beneficial. It was largely the benefit arising from certain of these cases that directed attention to the idea of inducing collapse artificially. In most cases of spontaneous pneumothorax the pleura becomes inflamed, and fluid, whether thin or purulent, transforms the condition into a hydro- or pyro-pneumothorax.

*Artificial Pneumothorax.*—Otherwise known as pneumothorax treatment, or as collapse-therapy, artificial pneumothorax was first urged on theoretical grounds in 1821 by an Irishman, James Carson of Liverpool. His views were supported by clinical observations on Spontaneous Pneumothorax (Houghton, 1832; Stokes, 1837), but not till 50 years later did Potain (1884) put air into a spontaneous pneumothorax, and Cayley (1885) treat a case of haemoptysis by this method. The treatment on its modern lines may be said to originate with Forlanini, who reported his first cases in 1894–5.

The aim of this treatment is the collapse of a diseased lung, where disease does not respond to other measures, and where the other lung is sufficiently sound. Its main field has been pulmonary tuberculosis, but it has also been used in lung abscess and bronchiectasis, in the diagnosis of obscure lung conditions, especially tumours, and to assist the surgeon in certain chest operations. The gases used are commonly air, nitrogen or oxygen, according to the requirements of the case.

The gas is delivered from a "gas bottle" connected with a "pressure bottle" containing fluid, and enters the chest through a special needle attached to a water manometer to control the pressure. It is introduced in small quantities at first and collapse brought about slowly. As it collapses the lung squeezes out the diseased secretions it contains, and these are brought up as sputum. In a favourable case the sputum then ceases, the temperature becomes normal and the patient regains his lost health. Gas is given every few weeks, and treatment is carried on till disease is judged to be healed. The lung is then allowed to expand and does so to a varying extent. The main impediment to pneumothorax treatment is the occurrence, in a large proportion of cases, of adhesions between the surfaces of the pleura. The main source of failure during its course is the development of fresh disease in the functioning lung. The success of pneumothorax treatment in severe tuberculous disease has been very notable, at least 50% being improved, arrested or cured.

**POELZIG, HANS** (1860– ), German architect, was born in Berlin April 30 1860. He studied architecture at the technical high school in Berlin from 1888 to 1893, in 1900 he was appointed a lecturer in the Breslau Academy of Arts, of which he was subsequently director from 1903 to 1916. He was architect to the city of Dresden from 1916 to 1920 and also professor at the technical high school there. In 1920 he started an advanced studio for applied arts at the Academy of Arts in Berlin. He became professor of the architectural section of the Technische Hochschule in Berlin in 1924. Poelzig was also a member of the Academies of Arts at Dresden and Berlin and president of the Deutscher Werkbund. Among his buildings may be mentioned the dam in the Klingenberg Valley; the Centenary Exhibition in Berlin (gardens and buildings); the reconstruction of the Schauspielhaus, Berlin; the water tower at Posen; the "Capitol" Cinema, Berlin; the Reick gas works, Dresden; and the alterations in the Breslau concert hall.

**POINCARÉ, JULES HENRI** (1854–1912), French physicist, was born at Nancy April 29 1854. He studied at the École Polytechnique, devoting himself to scientific mining, and took his degree in 1879. He was lecturer at Caen and then was transferred to the University of Paris in 1881, lecturing first on physical mechanics, then on mathematical physics, and ultimately on astronomical mechanics. In 1887 he became a member of the Académie des Sciences. Among the discoveries made

by him is that of the "Fuchsian functions," an order of functions more general than those of the ellipse, which he applied to the non-Euclidian geometry founded by Lobatchevski, and that of the theory concerning the rings of Saturn, by which they are supposed to be formed of a multitude of small and solid satellites. He also worked on the electro-magnetic theory of light and on electric oscillations. Poincaré died in Paris July 17, 1912. His works include *Cours de physique mathématique*, 10 vol. (1889 etc.); *Leçons de la mécanique céleste* (1905 etc.); *Théorie de Maxwell et les oscillations hertziennes* (1907); *La théorie du potentiel newtonien* (1899); *Science et hypothèse* (1903); *La valeur de la science* (1904); *Science et méthode* (1908).

**POINCARÉ, RAYMOND** (1860-1912), French statesman (see 21.892). In March 1906 M. Poincaré became Minister of Finance in the Sarrien Govt., but he gave up his portfolio to M. Caillaux in Oct. of the same year, when M. Sarrien was succeeded by M. Clemenceau as Prime Minister. During the next five years, though he still continued to exercise a powerful influence in the Senate, M. Poincaré devoted himself mainly to his legal career. In 1909 he was elected a member of the French Academy. In Jan. 1912, M. Caillaux, who had been Prime Minister since the beginning of the previous year, resigned, whereupon M. Poincaré formed a government in which he himself held the portfolio of Foreign Affairs. His most notable colleagues were M. Millerand, M. Briand and M. Delcassé, Ministers of War, Justice and Marine respectively.

M. Poincaré's Cabinet constituted an *entente nationale*, and his first aim was to pursue a more definite foreign policy. In home affairs the problem which presented the greatest difficulties was that of electoral reform. M. Poincaré induced the Chamber to pass a proportional representation bill. But above all diplomatic affairs claimed his constant attention; for during the negotiations with Germany which took place in consequence of the dispatch of a gun-boat by that country to Agadir, certain incidents had occurred during the Caillaux administration which had produced a feeling of disquietude in regard to foreign policy. M. Poincaré therefore sought to re-establish a continuity of policy; and though he maintained courteous relations with Germany his main endeavour was to prove that France would remain faithful to both friends and allies. The ratification by the Senate of the Franco-German Treaty of Nov. 4 1911 was followed by France's definite establishment in Morocco and on March 30 1912 M. Poincaré obtained the signature of the Sultan Mulai-Hafid to a treaty recognising the French protectorate. On Nov. 27 he further concluded a treaty with Spain which settled the boundaries of France and Spain in Morocco.

Almost immediately after the establishment of the Poincaré Govt., an incident had occurred, which temporarily obscured the friendly relations between France and Italy. The Italians, who at that moment were at war with the Turks, seized two French mail-steamer, the "*Carthage*," and the "*Manouba*," which were on their way to Tunis, on Jan. 16 and 18 1912. But M. Poincaré, by his calmness and resolution, succeeded in re-establishing amicable relations between the two countries. By the end of Oct. Italian sovereignty in Libya was recognised, and by a mutual declaration of the two Governments, full liberty of action was granted to France in Morocco and to Italy in Libya. When in the autumn of 1912 the Balkan War broke out, M. Poincaré made every effort possible to prevent the conflagration from spreading. Nevertheless, the succession of European crises combined with the ever-increasing menace from Germany and Austria-Hungary, rendered it necessary to take precautions; and with this object in view, M. Poincaré exercised constant watchfulness over army organisation. He induced Parliament to vote a programme of naval construction; and through the strengthening of Franco-British relations it became possible to concentrate the whole of the French fleet in the Mediterranean while Great Britain disposed her naval forces in the North.

At the beginning of Jan. 1913, M. Poincaré made known his intention of standing as a candidate for the presidency of the republic in the place of M. Fallières. A rival candidate appeared in

the person of M. Pams, the Minister of Agriculture, who was supported by the Radicals and Socialists. The contest between the two was spirited, but on Jan. 17 the National Assembly elected M. Poincaré President of the Republic by 483 votes, as against 296 votes for M. Pams. M. Poincaré on being elected resigned the premiership, and was replaced by M. Briand. On Feb. 18, the date when M. Fallières' term of office expired, the new president took up his residence at the Elysée. Two days later he addressed a message to Parliament, reminding them among other things that "the will of one power alone was not enough to maintain peace," and "any nation that wished to give proof of its pacifist attitude must be ready at all times to meet and repulse any military attack which might be made against it." This allusion to the danger of war showed that the new president was fully alive to its possibility; and that this fear was well grounded events were soon to justify. Seeing that the menace from without continued to increase, M. Poincaré felt that while adhering strictly to the limits imposed upon his powers by the French constitution, his first duty must be to back up all those who were endeavouring to strengthen the defensive organisation of the country. Never once did he exceed his functions in this respect, and the men to whom he entrusted the government were always those who had the support of Parliament.

Always apprehensive, and with reason, of the terrible events which he saw were looming ahead, M. Poincaré endeavoured to cement the friendships and strengthen the alliances of France. At a later stage, his adversaries abroad as well as those at home criticised him severely for this policy; yet it is hardly reasonable because a man is sufficiently far-seeing to apprehend a storm and make preparations for it, to accuse him of wishing to hasten it. He claimed that he did his utmost to avert war holding that the way to prevent the conflict was for those powers against whom the menace was directed to present a powerful and united front, and thus make it seem imprudent to attempt any act of aggression. He also felt that if in spite of everything France was attacked, it was essential for her to be able to make a successful resistance. This belief he consistently adhered to, both in deed and word, as well as in his writings; and though it impelled him to be constantly on his guard, he never departed from a strictly pacifist attitude.

In July 1914 M. Poincaré went to Russia on a visit which had been planned for some time past. He was on his way home, having arranged to visit the three Scandinavian capitals, when the news of the Austrian ultimatum to Serbia reached him. After a short stay in Stockholm he returned hastily to Paris; and in a letter to King George V. he pleaded for a clear declaration that the *entente cordiale*, if necessary, would prove its strength on the battlefield, pointing out that such a statement would have a restraining effect on the policy of Vienna and Berlin. Throughout the War he continued to perform his duty with the same energy and discretion as before; though sometimes he visited the front, he never placed any obstacle whatever in the way either of the Government or of the army. In Nov. 1917 he gave proof of his vision and disregard of self by placing in power M. Clemenceau, who, though undoubtedly the man of the moment, was one with whom he had little sympathy. During the critical months of 1918, M. Poincaré revealed an inflexible resolution and a supreme confidence in the ultimate victory. After the Armistice, Parliament by a resolution testified to the services he had rendered to his country.

During the peace negotiations divergence of views again became apparent between M. Poincaré and M. Clemenceau. On more than one occasion the president found it necessary to write to the Prime Minister pointing out the errors which, from his point of view, were being committed. His counsels, however, were not followed, and at the beginning of 1920, after having completed seven years as president, he left the Elysée and was shortly after re-elected senator for the department of the Meuse. In Jan. 1922, the Briand Cabinet having resigned, M. Poincaré once more became Prime Minister and Minister for Foreign Affairs. He made it his chief aim to insist on the fulfilment by Germany of her obligations in regard to reparations. During

the first year of his new Government he failed to arrive at any agreement on this subject with the British Cabinet, whose views differed so widely from his own. The Inter-Allied Conference in London in Aug. and Dec. 1922 produced no result. A further conference took place in Paris on Jan. 2 and 5 1923. But M. Poincaré rejected the proposals drawn up by Mr. Bonar Law, and all that was done was to put on record, in friendly terms, the complete disagreement of the two Governments.

At this moment, the Reparations Commission, with Britain dissenting, having declared that Germany had failed to fulfil her obligations in regard to the delivery of coal and coke, M. Poincaré, in agreement with Belgium, undertook the occupation of the Ruhr. At first this measure involved merely a method of control, but gradually, owing to the passive resistance of the Germans, it became necessary to exploit the railways and to some extent also the mines by means of Franco-British supervision. By the autumn the passive resistance had ceased, and M. Poincaré awaited the German proposals which never came. He then accepted the American suggestion that a group of experts should be given the task of finding the solution of the reparation problem; this resulted in the adoption of the Dawes Plan. But M. Poincaré had made up his mind not to withdraw from the Ruhr until he was satisfied that this plan was being carried out.

During the first three months of 1924 M. Poincaré had to face a financial crisis due to the state of the exchange. Not without difficulty he induced Parliament to vote new taxes and succeeded in saving the situation. But from now onwards he had to withstand strenuous opposition from the parties of the Left consisting of the Radicals and Socialists. The policy of these groups met with a marked success at the general elections of May 11 1924 and resulted in a majority for the Left which now formed a coalition under the name of the Cartel des Gauches. Immediately the results were announced, M. Poincaré stated that he would retire on the day when the new Chamber was to assemble, which took place on June 1 1924. Thereafter he took his place in the Senate, intervening only rarely in political debates. In addition to various articles on legal, political and literary subjects, Poincaré undertook the publication of an important work in 10 volumes, entitled: *Au service de la France; neuf années de souvenirs*, the plan of which is to describe the sequence of events from 1911 to 1920 and the rôle which he himself played in them. Two of these volumes appeared in 1926 under the titles of *Le lendemain d'Agadir* and *Les Balkans en feu*.<sup>1</sup>

**POLAND** (see 21.002), an independent Republic of Central Europe (Rzeczpospolita Polska) and a member of the League of Nations. Its area is 149,895 sq. m., and the population (1925) 28,896,000.

## I. POLITICAL HISTORY

*Poland After the Partitions.*—The Congress of Vienna (1815) set the seal on the three partitions of Poland. The smouldering discontent of the Poles broke out in revolution in 1830, 1846 and 1863; but the bloody repression of the last revolt closed the period of active rebellion. From this date until 1914 the Poles of Prussia, Galicia and Congress (Russian) Poland developed along widely different lines so that from a practical standpoint the differences between them became almost as important as the ideal unity of their memory and dreams.

*The Poles in Prussia.*—Each acquired some characteristics of the Empire with which its lot was cast. The Prussian Govt. especially under Bismarck, had attacked the Polish problem with its usual efficiency. In the 'thirties the administration in Prussian Poland had become purely German; the Polish officials

<sup>1</sup>In June, 1926 when the fall of the Briand Government created great confusion in France, Poincaré declined to join Briand in a reconstructed cabinet. However, after the brief administration of Herriot, he became head of a coalition government, undertaking himself the onerous duties of minister of finance.

assisting this process by quitting the State service. In 1872 the "Kulturkampf" began; the Polish language was gradually eliminated from school and pulpit. In 1886 a commission began to buy up Polish estates and settle German peasants on them. In 1894 the "Ostmark" organisation was founded, with the aim of ensuring German cultural and mercantile predominance in the East. In 1902 the so-called "Wrzesnia" case aroused a painful scandal when it was admitted in the German Reichstag that Polish children had been beaten for refusing to say the Lord's Prayer in German (see POSEN, 22.170). In 1908 a compulsory Appropriation bill was passed, and the use of Polish at public meetings forbidden. The resistance of the Poles was stubborn, but in view of the strength of Germany, not mainly political. The leaders looked to Russian Poland for assistance; but their strength at home lay in the network of co-operatives and peasants' associations, led by the Catholic priests, who put up a solid resistance in the economic field. The result of the Prussian occupation was to create a sturdy class of peasants and small bourgeoisie, disciplined and economically and culturally advanced, whose political programme was essentially defensive.

*The Poles in Austria.*—In Austria, on the other hand, the Poles were almost a dominant nationality. The numerical strength of the Parliamentary "Polenklub," which always united against all outsiders, was such that no Austrian Govt. could be formed without it. In 1867 the Poles of Galicia were granted a special Minister for Galicia (Galizischer Landsmannminister) as the price of their consent to the "Ausgleich" with Hungary. The Governor, or Statthalter, of Galicia was invariably a rich Polish aristocrat; and these two officials were able to defy any centralising efforts of the Vienna bureaucracy and establish a *de facto* independent Polish State within Austria, with a purely Polish administration, which extended over non-Polish East Galicia. Galicia, unlike Prussian or Congress Poland, thus retained an active interest in politics, and the nobles developed into a large administrative class; but while preserving the tradition of the "Szlachta" they paid little attention to material development; and Galicia remained economically backward in every respect. Even the development of the Galician oil-fields, when it came, was due almost entirely to Jewish houses, who made enormous fortunes out of it. *De jure* autonomy within the monarchy for Galicia was constantly urged by the German nationalists of Austria; but would have been most unwelcome to the Poles, politically, because it would have vastly weakened their position against the Ruthenes of East Galicia (see GALICIA, EAST) who were almost as numerous as themselves; financially even more, because it would have meant the end of the very heavy annual subsidies which this province received from the Imperial Exchequer.

*The Poles in Russia.*—Nor was the desire for a free and united Poland so unresting in Warsaw as is generally supposed. All self-government in Congress Poland was suppressed in 1863; all education was Russified in 1869, justice in 1873. On the other hand, the abolition in 1851 of the customs frontier between Russia and Poland had laid the foundation for an extraordinary industrial expansion in this district. Russian Poland became the chief industrial region for all Russia. Its vast market in agricultural Russia was protected against Western competition by high tariffs; the Russian Govt. took every possible measure (such as the introduction of specially favourable railway tariffs) to assist this expansion. The Poles of Russia refused on principle to enter the Russian State service. This could only be welcome to Russia; and its result was that the Poles busied themselves with productive occupations—industry, trade and agriculture, and the upper and middle classes achieved a well-being far superior to anything enjoyed by their cousins in Galicia. A second and important result of this expansion was the growth in Congress Poland of a large and radical proletariat which dissociated itself from its Polish exploiters and made common cause with the Russian Social Democratic movement. The divisions between the upper and lower classes in Poland were accentuated by the agrarian policy of the Russian Govt. in Poland. The emancipation of the peasants was effected by

the ukases of 1861. Each peasant, whatever his tenure had been, and the mass of the landless proletariat, became freeholders. The landlords received compensation in the form of Russian Treasury Bonds. Village affairs were placed in the hands of the peasants' communes, which quickly fell under the influence of Russian bureaucracy. Nevertheless, contrary to the hopes of the Russian Govt., these communes served as centres for the spread of education and for the revival of the idea of Polish nationality.

The Russian revolution of 1905 was a turning point in Polish history. The measures of repression which followed it aroused the deep hatred of a large section of Poles among whom the most prominent was Piłsudski, leader of the "right" or patriotic wing of the Socialist party, who was obliged to flee to Galicia and now began to organise active resistance to Russia

from that base. Yet the revolution was followed by the grant of a Russian Constitution, and the Liberals in the Duma were not averse to the idea of granting Poland a large measure of autonomy within Russia. The Polish and the Russian bourgeoisie found a bond of union, even as had the Polish and Russian proletariat. Moreover, the brighter prospects in Russia contrasted strongly with the renewed severity of the régime which Bülow introduced in Prussia. And in East Galicia and the Ukraine alike the Ukrainian (Ruthenian) nationalist movement—much more prominent in Austria since the grant of general suffrage in 1907—was exceedingly unwelcome to both the Poles and the Russians.

Russia, defeated in the Far East, had again begun, after an interval of nearly 30 years, to propagate Pan-Slav ideas and to work actively among the Slavs of Europe. The Neo-Slav move-

ment, unlike most earlier forms of Pan-Slavism, was prepared to drop the racial and religious feud with the Poles. The idea of uniting all Poles with autonomy within the Russian Empire was widely preached; its realisation seemed near at hand. It became the programme of the National Democratic (All-Polish) party, founded in Congress Poland in 1897 under Roman Dmowski, which gained a considerable following, even in Austria. The Slav Congresses of 1908 and 1910 really did much—thanks largely to the efforts of the Young Czech leader, Dr. Kramář, to reconcile the Polish and Russian nations. This reconciliation, was not, indeed, more than partial. It was rudely shaken in 1912, when Russia separated the Govt. of Cholm from the rest of the Kingdom of Poland. Poles in general, nevertheless, now looked on Prussia as their chief enemy and the sympathies of the Poles of Galicia had become divided.

*Poland During the World War.*—The outbreak of War in Aug. 1914 thus found the Poles of Germany, Austria and Russia to a great extent estranged from one another, their sympathies divided, and a united national policy lacking. Piłsudski, the "activist," crossed the frontier from Galicia with a few hundreds of his armed band and engaged the Russian Empire in battle as forerunner of the army of an independent and united Poland. But the Polish National Committee, formed in Cracow on Aug. 16, aimed at uniting Galicia and Congress Poland as a third party in the Dual Monarchy and required the Polish Legion to take the oath to the Emperor. In Warsaw another Polish Committee under Dmowski denied the right of the Cracow Committee to speak in the name of the Polish nation; protested loyalty to the Tsar; and attempted to form a Polish Legion on the side of Russia. Meanwhile the Grand Duke Nikolai Nikolaievich issued a proclamation (Aug. 14) in which he promised to unite the three parts of Poland in an autonomous state with the Russian Empire. When the Russian Army occupied a great part of Galicia the Russophil party in Galicia (the National Democrats) openly adhered to this programme. The "Austrian Solution" retired into the background.

In the summer of 1915, however, the Central Powers conquered all Congress Poland. After the fall of Warsaw on Aug. 5 1915, governments were set up on behalf of Germany at Warsaw, and Austria-Hungary at Lublin. It was now the Russian solution that was platonic. But fresh difficulties confronted the Austrian solution. The Polish Socialist Party (P.S.P.) under Piłsudski declared that no recruiting should take place for Polish legions until an autonomous Polish Govt. had been formed to conduct it. The P.S.P., the Peasants' Party and the National Democrats united on this programme. Meanwhile Tisza, the Hungarian Minister President, had vetoed the Austrian trialist scheme, which was also opposed by Germany. Vienna, again, rejected the plans put forward by Germany, of annexing Congress Poland to Germany, or of forming an independent Polish buffer state in economic military and political alliance with the Central Powers.

*Formation of a Polish State.*—In Aug. 1916, however, after the defeat of the Austro-Hungarian troops at Łuck, the German Supreme Command acquired complete control of policy on the Eastern Front. Ludendorff believed it possible to gain a large Polish Army if his ideas were adopted. Germany and Austria-Hungary issued a proclamation on Nov. 5 1916, holding out a prospect of the restoration of an independent Congress Poland as a hereditary constitutional monarchy closely attached to the Central Powers. Francis Joseph promised Galicia increased autonomy within Austria-Hungary. The discussion of details was shelved; the military governments at Warsaw and Lublin continued to administer the country. The German Governor, General von Beseler, arranged for the election of a Diet with fairly extensive powers in local administration, education and justice. Meanwhile, by decree dated Nov. 26 1916, a Provisional Council of State was appointed, which was solemnly opened on Jan. 14 1917; but the National Democrats were excluded from it, the Minister of Political Affairs was allowed to hold relations with the Central Powers only, and the decisions of the Diet

could be overruled by Von Beseler. Piłsudski, who had long been in conflict with the German Supreme Command on the degree of independence which the Polish troops should enjoy, resigned his command, entered the Diet and began to work out the plans for a national Polish Army. He refused, however, to raise it for German use; and actually the German plan of raising a Polish Army failed completely.

In March 1917 the Russian dynasty fell. On March 30 the new Russian Govt. recognised Poland's right to self-determination and promised Poland its support in the creation of a new Polish State. These events altered the attitude of the Allies towards Poland, particularly as they were now reinforced by the entry of the United States into the War. The answer of the Entente Powers to the peace proposals of the Central Powers issued on Jan. 10 1917 had already declared their adhesion to the Tsar's manifesto to his armies (Dec. 25 1916) which had spoken of "the formation of a free Poland in all parts into which it is at present divided."

Paderewski was working tirelessly in America. In Nov. 1916 a great Polish National Department in Chicago had united all the organisations of the 4,000,000 Poles in America; and under Paderewski's influence, President Wilson on Jan. 22 1917 alluded to a "united, independent and autonomous Poland." The danger threatening Poland from Russia vanished with the breakdown of Brusilov's offensive (July 1917). The Central Powers were now the only enemy. The Poles of Galicia were discontented with Austria's failure to introduce the promised self-government; the Left was stimulated by the example of Russia, and when the Austrian Reichsrat met in May 1917, its Polish members demanded "an independent united Poland with an outlet to the sea," and declared that the Polish case was one for "international consideration." The Council of State in Warsaw demanded wider powers on May 1, but the chiefs of the Provisional Governments in their answers of May 15 and June 8 did not give immediate effect to these demands.

After a conflict, some members of the Council accepted the German demands to make a recruiting appeal, and take an oath of loyalty to the German and Austro-Hungarian armies and to their Allies, for the present War, swearing by their "Fatherland, the Kingdom of Poland and the future King of Poland." Piłsudski resigned from the Diet with his adherents, and set about turning his secret military organisation against Germany. Polish legions were formed in France under General Haller and in Russia under General Dowbor-Musicki. Polish volunteers from America were trained in Canada. On July 22 Polish discontent was increased by the arrest of Piłsudski. On Aug. 25 the Diet, now discredited with the people, resigned. On Sept. 12 Germany and Austria-Hungary introduced a new project of a regency of three, a Cabinet and Premier and Council of State, chosen by the regency, and enjoying limited powers, the German and Austrian military governments retaining the right of veto. The regency was appointed on Oct. 15; it consisted of the Archbishop of Warsaw, Dr. Kakowski, Prince Lubomirski and Josef Ritter von Ostrowski, a large landowner. The first Minister President, Jan v. Kucharzewski, was appointed on Nov. 26 and formed his first Ministry on Dec. 7.

The final collapse of the Russian Army in the autumn was the signal for the Central Powers to work out fresh combinations, according to which the future of Poland was determined in the most various ways. But although Germany was still strong, Austria had now lost all real authority over the Poles of Galicia, who were in a position to dictate terms as they pleased. The proposals of the Russian delegates who arrived at Brest-Litovsk in Dec. 1917 amounted to a recognition of Poland's independence; and the thirteenth of President Wilson's Fourteen Points (Jan. 8 1918) declared that a Polish State should be erected which should include the territories inhabited by indisputably Polish populations "with an outlet to the sea and an international guarantee of its independence and integrity." The Polish National Committee, founded at Lausanne in Aug. 1917 and since established in Paris, was gaining increasing influence in the councils of the Allies, largely through Paderewski, who represented it in

Washington. Between Sept. 20 and Dec. 1 1917 France, Great Britain, Italy and the United States had recognised it as the official representative of the Polish people. Polish delegates were not admitted to the deliberations at Brest-Litovsk.

By treaty (March 3) Russia renounced all claims over Poland; but the treaty signed Feb. 9 1918 between the Central Powers and the Ukraine allotted the Ukraine the disputed province of Chełm, while Austria-Hungary further pledged herself in a secret clause to form East Galicia and the Bukovina into a separate Crownland. These clauses became known; Polish opinion was infuriated beyond measure; the Polish Cabinet resigned; the Polish Club in the Austrian Reichsrat went over to the Opposition; the remnant of Piłsudski's legions still fighting for the Central Powers mutinied. Some were interned; some fought their way to the coast and joined Haller's legions in France. In April the Polish delegates to the Congress of Rome declared their aim to be "reunion into one independent State of all the Polish lands, including those which the Central Empires are refusing to restore to Poland and those which they are bestowing as largesse on their vassals." The elections for the Council of State in Poland were held in the same month; and it was opened in Warsaw on June 22. Little interest was taken in the elections, and general feeling in Poland tended to ignore this body in favour of the National Committee in Paris: After the breakdown of the German offensive in July 1918, a last effort was made. The Poles were offered their choice between rival schemes of a Poland attached to Austria in the "Mitteleuropa" plan, or a State formed according to German wishes, though under an Austrian Archduke. But the Poles were now strong enough to ignore all suggestions from this quarter, especially as the Prime Ministers of Great Britain, France and Italy had declared in favour of an independent and united Poland at Versailles on June 3 1918, and Wilson insisted on the Fourteen Points as a basis for peace.

*The Declaration of Independence.*—On Oct. 6 the Polish Regency Council and Minister President published a manifesto to the Polish nation declaring its intention of dissolving the Council of State, forming a representative national government and summoning a Diet for a "free and united Poland." On Oct. 15 the Polish representatives of the Reichsrat declared themselves to be "subjects and citizens of a free and re-united Polish State." On the same day the Council of Regency in Warsaw summoned the Galician Poles to Warsaw to take part in forming the new Polish Government. A Cabinet, consisting for the most part of Russophil National Democrats, was hurriedly formed on Oct. 22. On Oct. 28 a Commission of Austrian Poles met in Cracow to wind up relations with Austria. Assuming its authority to extend throughout Galicia, it appointed its next meeting for Nov. 2 in Lemberg, where a Ruthenian Govt. had already formed, thus early coming into collision with its neighbours (see GALICIA: EAST). On Nov. 3 the Cabinet proclaimed the Polish Republic, and declared its intention of forming a Government with the Left. In fact, owing to the hostility of the Left, the Cabinet resigned on Nov. 4, and a provisional Cabinet of officials carried on. On Nov. 10 Piłsudski, who had been released from imprisonment on Oct. 7, arrived in Warsaw. The German troops of occupation were disarmed and expelled, and the Poles assumed the executive power in Warsaw on Nov. 11. The Council of Regency declared on Nov. 12 that it appointed Piłsudski to the supreme command of all Polish troops; while Piłsudski proclaimed himself head of the National Government. On the 18th he notified all belligerent and neutral States of the formation of an independent State of Poland.

*Post-War Position.*—Of all the new or resurrected states of Europe, Poland was in many respects in the most difficult position. The territory of Congress Poland and Galicia had been devastated in the War. Most of the factories were closed for lack of raw material, where they had not been actually dismantled. The fields of the peasants had been laid waste, their live stock slaughtered, their farms burnt. Many districts were actually famine-stricken, others swept by epidemics. Communications were disorganised, rolling stock in a deplorable

state. Marks, roubles and kronen circulated freely, but their value was low and uncertain, and public and private finances were chaotic. Owing to the past policy of the Prussian and Russian Poles, a national bureaucracy only existed in Galicia. At one time there were only six officials in the Ministry of Finance. Thirty thousand German troops were still in the country. On the East, Bolshevik Russia was in a highly unsettled state. The ideas prevalent in Russia had unsettled the peasants, who pressed for a redistribution of land from the large estates, and the workmen, who were suffering under unemployment, were in a state of unrest. The century of foreign rule had been an ill training for constructive political thought, and political parties were as numerous as they were, in the main, futile.

But above all, the problem of Poland's frontiers assumed an immediate and lasting importance. Only in the Carpathians could Poland be said to possess a natural frontier. Over the vast and formless eastern plains, nation merged into nation, and there were vast areas where the very language of the inhabitants was only a doubtful dialect. In others, enclaves of Polish and non-Polish territory were inextricably mixed. In others, and these among the richest, the land-owning nobility was Polish, the peasants Ukrainian or White Russian. Poland's historical frontiers had at one time extended, over large non-Polish populations, from the Baltic to the Black Sea. At the time of the Partitions of Poland, they had embraced nearly twice as much territory as was ethnographically Polish. The Poles themselves had learned to think in wide spaces, with more force than restraint. With powerful neighbours to East and West, each far more numerous than themselves and each at the moment highly unpopular with the victors in the War, the Poles little needed the encouragement which they received to make enormous territorial claims. Much of their history for the next four years was to consist in disputes with their neighbours involving the young State in excessive expenditure and entailing grievous neglect of internal problems.

Piłsudski, the old revolutionary, had begun by appointing a Cabinet of the Left, composed mainly of Galician socialists and peasants' representatives. This was formed on Nov. 18 after the Social leader, Daszyński, had attempted unsuccessfully to form a ministry four days previously. The programme of M. Moraczewski, the Premier, was "consolidation and social construction." But his rule was short. The propertied classes refused him their support, and his attempt to float an internal loan met with little response. The friends of the Entente and the National Democrats resented the Galician rule; and when M. Paderewski, the second man in Poland enjoying almost unlimited prestige, arrived in the country in Dec., he composed his differences with Piłsudski and became Premier on Jan. 17. Prussian Poland had come under complete control of its Polish inhabitants by Jan. 9. West Galicia was incorporated; East Galicia was occupied by Polish troops, which had entered Lemberg on Nov. 22. It was possible to hold elections for a Constituent Assembly on Jan. 26 1919. The Constituent Sejm met on Feb. 10. Out of the 337 deputies, only 32 were Socialists. The National Democrats numbered 107. The majority of the House consisted of peasants, politically extremely ignorant, sympathising with the Left against the landowners, with the Right against Socialism. The Sejm passed a vote of confidence in Paderewski's Cabinet, and confirmed Piłsudski in his position as head of the State without, however, exactly defining his position.

Piłsudski and Paderewski were chiefly interested in foreign affairs. On Dec. 13 1918 Poland had broken off diplomatic relations with Russia, on Dec. 15 with Germany. On Jan. 4 1919 all Polish parties had issued a message that Poland was one with the Entente through community of ideas and historical tradition. Paderewski proceeded to Paris to urge Poland's claims; Piłsudski raised an army to defend them. General Haller's troops, returning from France, formed the nucleus of this force. The unemployed were glad to join it and on March 7 six classes were called up. Already Poland had an army of

600,000, which was soon increased to 800,000. On April 2 a state of siege was proclaimed in Congress Poland, and on May 8 an offensive opened in East Galicia against the Soviet Russian and Ukrainian forces.

*The Treaty of Versailles and the Frontier Problems.*—On June 28 1919 the Polish delegation signed the Treaty of Versailles, under which Poland agreed to accept an agreement with the Principal Allied and Associated Powers for the protection of national minorities in Poland, and for the protection of freedom of transit and equitable treatment of the commerce of other nations. This Minorities Treaty was signed on June 28 1919 between Poland and the Principal Allied and Associated Powers. Under the Treaty of Versailles, Poland received the larger part of Posen and part of West Prussia. A plebiscite was to determine the settlement of Masuria and Upper Silesia. Danzig was to be a free city under the protection of the League of Nations. This city was to be included within the Polish customs frontiers and its foreign relations and the protection of its citizens abroad were to be entrusted to Poland, who also received other economic rights in this territory. The actual details were to be settled later by a treaty between Poland and the free city. Art. 87 of the Treaty assigned to the Allied and Associated Powers the duty of fixing Poland's eastern frontier. A provisional boundary was laid down between Poland and Russia, roughly corresponding to the course of the Vistula. As a signatory to the Treaty of Versailles, Poland was an original member of the League of Nations. The treaty was not popular in Poland but the Sejm ratified it on July 30–31 by 285 votes to 41. During the next three years, however, Poland was almost exclusively occupied on questions arising directly or indirectly out of it, which it will be convenient to take in order.

The industrial district of Teschen (*q.v.*), with important coal mines, was claimed by both Poles and Czechoslovaks. Each nation attempted to assume practical control and there was some fighting. A plebiscite commission arrived in the district on Jan. 30 1920, but on July 28 1920 the Supreme Council fixed a line of demarcation through this district, cutting the town in two, and through the neighbouring districts of Zips and Orava. In East and West Prussia (*see ALLENSTEIN-MARIENWERDER*) the plebiscites were held on July 11 1920. The bulk of the districts were allotted to Germany on the basis of the vote.

Upper Silesia was the scene of grave troubles (*see SILESIA, UPPER*). Art. 88 of the Treaty of Versailles provided that the inhabitants of this area, except in its purely German portions, should vote by plebiscite for adherence to Germany or Poland. Allied troops occupied the districts in the meantime, and a commission consisting of a French, a British and an Italian representative took charge. The plebiscite was fixed for March 20 1921. The Poles put great pressure on the inhabitants. At the polls, 717,422 votes were cast for Germany, 483,514 for Poland. The towns and industrial districts voted German. In consequence of a rumour that only two districts were to be assigned to Poland, Korfanty, a prominent Pole, occupied southeastern Upper Silesia with an armed force, recruited and equipped from Poland, and defied the Allied Powers. A commission of the Council of the League of Nations on Oct. 20 1921 awarded the southeastern districts, including 75% of the aggregate material wealth of the disputed territory, to Poland. A convention signed at Geneva between Poland and Germany May 15 1922 provided guarantees for the continuity of the economic life of the country and the protection of minorities during a transitional period of 15 years.

Danzig (*q.v.*) was proclaimed an independent free city on Nov. 15 1920. A treaty between Danzig and Poland was signed at Paris Oct. 27 1920 and a supplementary convention at Warsaw Oct. 24 1921. Poland's rights in the territory of the free city are exclusively economic and ensure her free access to the sea. The convention regulating the administration of the harbour and waterways was signed on May 23 1923.

*Hostilities Against the Ukraine and Russia.*—The disturbances on Poland's eastern frontier were on a larger scale. Polish troops, on occupying Lemberg in Nov. 1918, had expelled the East

Galician Govt., which took refuge in Vienna. General Petliura, who formed a government in the Ukraine in the same month, proclaimed the union of the Republics of Ukraine and West Ukraine (East Galicia). The East Galician troops placed themselves under his command. Throughout 1919 fighting continued between the Polish and Ukrainian troops, the former remaining in *de facto* possession of the disputed territory. At the same time, Poland was engaged in a somewhat serious war with Soviet Russia.

The German troops of occupation had evacuated the White Russian and Little Russian territory in Chełm and Volhynia in such a way that the Bolshevik troops were able to occupy it before the Poles, to whom the inhabitants appealed for aid, could come up. In this year Soviet Russia was engaged in war with most of her neighbours and with various expeditions, such as those of Kolchak or Denikin. The policy of the Allies was extremely uncertain; but in any case it was hostile to Soviet Russia, and there was talk of forming a "sanitary cordon" round that country. The Polish forces, as the largest and most successful of those opposed to Russia, enjoyed considerable support in Western Europe. All the Allies desired a strong Poland; but British statesmen considered that this aim would be best achieved if Poland's frontiers were not excessively extended. In the autumn, Russia suggested an armistice which was declined. The Allied and Associated Powers on May 8 definitely assigned West Galicia to Poland, and on June 21 allowed her to establish a government in East Galicia, which district was, however, to determine its own fate in the future and to preserve its autonomy. On Nov. 20 the Peace Conference reached a decision that East Galicia was to receive autonomy for 25 years under a Polish protectorate, after which period the League of Nations would decide its future.

The "Curzon line" of Dec. 8 attempted to define Poland's eastern frontier. It drew a line roughly following the ethnographical frontier and thus running some way further west than the actual line then occupied by Polish troops. The district of Vilna (Wilno), which the Poles had occupied in April 1919, was assigned to Lithuania.

In the spring of 1920 efforts were made to secure peace with Russia; but as Poland advanced claims on historical grounds to large non-Polish areas, these came to nothing. On April 25, having settled differences with Petliura in the Ukraine by a Treaty dated April 22, Poland opened a strong offensive. On May 8 the Polish troops entered Kiev. The Soviet Army, however, having defeated Kolchak and Denikin, concentrated against Poland and opened a counter-offensive. By July the Polish forces were in a serious position. Poland appealed to the Allies for mediation; and the Allies suggested that Poland should retire to the Curzon line and that representatives of Poland, Russia, Finland, Lithuania and Latvia should meet in London to arrive at a general peace settlement of eastern Europe. Russia refused this offer, but agreed to negotiate directly with Poland. On July 22 Poland asked Russia for an armistice; the Soviet Govt. replied, fixing the opening of negotiations. Russia was procrastinating, apparently believing that the military situation would become more advantageous to herself with delay.

The Allies, however, had been perturbed by the Russian advance, and a French mission under Gen. Weygand had arrived in Warsaw to assist the Polish General Staff. The invasion had also awakened Poland to the need of a supreme effort. The Government issued an appeal to the country, which responded to it nobly. On Aug. 14 Piłsudski opened a counter-offensive, and drove the Russians back in confusion. On Aug. 17 the Polish army retook Nowo-Mińsk and on Aug. 19 Brest-Litovsk. Poland, backed by the Allies, was now able to reject the terms which the Russian delegates at Minsk suggested, which included the formation of a civic militia of the Polish workmen, 200,000 strong. The conference was moved to Riga, where the preliminary treaty of peace was signed on Oct. 12. The final treaty was signed at Riga on March 18 1921 and ratified by the Sejm on April 17.

The contracting parties acknowledged each other's independence, and abandoned all claims to territories situated on the other side of the new frontier; Russia also declared her *désintéressement* as regards the territory disputed between Poland and Lithuania. Both parties mutually agreed to recognise the political sovereignty of the other and to refrain from propaganda or from harbouring organisations directed against the other party. They mutually renounced claims to war reparations, while Russia undertook to restore all art collections, libraries, historical documents, etc., removed after 1772, all industrial installation evacuated between Aug. 1 1914 and Oct. 1 1915, and to pay 30,000,000 roubles in gold as Poland's share in the assets of the former Russian Empire. A number of mixed commissions were set up to carry out the terms of this treaty; but, in general, disputes were more common than agreements among them. As regards industrial property, Poland agreed (Aug. 25 1914) to accept a large sum as settlement.

Poland's eastern frontier now ran southeast from the border of Latvia to Dżina (Disna), then south, just east of Dokszyce (Dokshitsi). It passes some 18 m. west of Minsk and, further south, some 70 m. east of Pinsk; then running almost due south and then slightly southwest to Ostrog; for some 25 m. it continues southwest, thence almost due south till reaching the river Zbrucz which it follows till its junction with the Dniester, which separates Poland from Rumania.

Simultaneously, Poland was embroiled with Lithuania on the question of Vilna (*q.v.*). This town and district had been occupied by Poland on April 19 1919 but were assigned to Lithuania by the Curzon line, and Russia recognised Lithuania's claims to them by a treaty dated July 12 1920. During their advance, Polish troops came into conflict with the Lithuanians. An armistice convention of Oct. 7 laid down a line of demarcation, which was to come into force on Oct. 10. On Oct. 9, however, the Polish General Zeligowski took possession of the disputed districts by a *coup de main*. The Polish Govt. disowned the General but made no serious effort to recall him. After prolonged negotiations, the Conference of Ambassadors assigned Wilno and district to Poland on March 14 1923. The Lithuanian Govt. refused to accept this decision as final. On March 14 1923 the Allied Powers through the Conference of Ambassadors recognised Poland's *de facto* northern, eastern and southeastern frontiers, the United States subsequently notifying the Polish Govt. of their acknowledgment of this fact. This decision repealed previous provisions for the future of East Galicia, which thus became an integral part of Poland.

*Relations with the Little Entente, France and Rumania and the Baltic States.*—Surrounded by so many enemies, Poland could not stand alone. The most important bloc in Central Europe formed after the War was that of the Little Entente (*q.v.*). Although Poland had many interests in common with the members of this alliance, she was unable to join it. She had no quarrel with Hungary; indeed, policy, tradition and a similarity of social structure made her sympathetic towards that State. The long drawn out disputes with Czechoslovakia on the Teschen, Zips and Javorzina frontier questions prevented a close alliance with that Power, which also refused to enter any alliance directed against Russia. Furthermore, Czechoslovakia had received a mandate over Carpathian Russia and hoped to establish a direct frontier with Russia. So long as the fate of East Galicia remained in abeyance Czechoslovak and Polish interests were bound to conflict.

On Nov. 6 1921 a Czecho-Polish political convention was indeed signed at Prague. The two parties mutually guaranteed, as far as they were able, the territories in their possession and agreed to act in concert for the application of the treaties which they had signed in common "when occasion arose." Czechoslovakia "disinterested herself" in Eastern Galicia, Poland undertook "analogous obligations" towards Czechoslovakia. Note was taken of Czechoslovakia's conventions with Rumania and Yugoslavia, Poland's with France and Rumania; reference was made to a commercial convention, and provision made for arbitration of differences. Feeling, however, was too unfriendly for the ratification of the treaty, although a commercial agreement was signed (Sept. 20 1921). Poland took part from time to time, as observer, in the periodical conferences of the Little Entente. Poland's relations with Czechoslovakia only became really cordial in 1925.

Of much greater importance were Poland's agreements with France and Rumania, referred to above. From the first, France had designated Poland as the Ally which should take over

Russia's rôle on Germany's eastern frontier. The note with which Clemenceau transmitted to M. Paderewski the Polish Minorities Treaty reminded him that Poland would "to a large extent depend for the secure possession" of her territories on the Western Powers. The French Mission helped to save Poland during the Russian advance of 1920. France gave Poland her support in the Silesian and East Galician questions, thus helping her to acquire most valuable coal and oil fields and industrial regions. France assisted Poland to organise and equip her army, lent her instructors and staff officers and made her generous loans for the purchase of war material. On Feb. 19 1921 Piłsudski signed a Franco-Polish Treaty in Paris for the "maintenance of the treaties . . . the peace of Europe, the security of their territories and their common political and military interests." The two Governments undertook to consult each other "in all matters of foreign policy which concerned both States so far as these questions affect the settlement of international relations in the spirit of the treaties and in accordance with the Covenant of the League of Nations"; to conclude a commercial treaty and to take concerted measures "for the defence of their territories and the protection of their legitimate interests" in cases of an unprovoked attack upon either or both.<sup>1</sup>

The Polish Govt. ratified this political treaty on May 30 1922. It was not stated whether any further unpublished military convention had been concluded. Poland signed a commercial agreement with France (Feb. 6 1922) with a bilateral convention dealing with the property and rights of private individuals and an agreement concerning the exploitation of oil in Poland. A new convention was signed in Paris on Dec. 9 1924 on a very wide basis, which again included clauses relating to the French capital invested in Polish oil. Other agreements with France deal with the Polish immigrant workmen in France (Sept. 3 1919 and Oct. 14 1920) and consular and general matters (April 17 1924, Dec. 30 1925, Feb. 20 1926).

In view of the common danger threatening both States from Russia, Poland concluded a defensive alliance with Rumania on March 3 1921 (text printed in vol. 7 of the League of Nations Treaty Series). The treaty provided for mutual assistance in the case of an unprovoked attack on either party on their eastern frontier (defined in the case of Poland as those laid down in the preliminary Treaty of Riga of Oct. 12 1920); common diplomatic action in regard to the two parties' eastern neighbours; and for a military convention to be concluded for the same duration as the treaty, *i.e.*, five years from the date of signature, with the right of denunciation at six months' notice after two years.

A definite alliance between Poland and the Baltic States proved impracticable as, quite apart from the antagonism between Poland and Lithuania, the smaller states could not contemplate anything but a defensive attitude towards Russia, and feared to be entangled in an aggressive policy. In July 1921, however, representatives of Poland, Finland, Latvia and Estonia met at Helsingfors and determined to hold periodical conferences to exchange opinions on matters of policy and discuss the possibility of joint action. Such conferences were held at Riga (Aug.-Sept. 1921), Revel (Dec. 1921), Warsaw (March 1922), Genoa (April 1922), Revel (Sept. 1922), Helsingfors (March 1923), Riga (July 1923), Revel (Oct. 1923), Warsaw (Feb. 1924) and Helsingfors (Jan. 1925). The majority of these dealt only with minor financial and economic problems. At the Warsaw Conference of March 1922, however, a political agreement was suggested defining the outlines of a *rapprochement* between the States concerned on the basis of "benevolent neutrality towards any of the signatory states which might be attached without provocation," and a previous understanding in respect of treaties and agreements entered into. These suggestions could not be ratified owing to the opposition of the Finnish Diet. A conference was held in the same month at Riga, attended also by representatives of Russia, where the establishment of neutral zones as a preliminary to disarmament broke down, as did the disarmament conference in Moscow of Dec. 1922. At the second Helsingfors conference (Jan. 1925) a multilateral arbitration treaty was signed between Poland and the Baltic States. Poland concluded a commercial treaty with Finland (Nov. 1923), a consular convention with Latvia (Jan. 3 1924) and with Estonia (Jan. 11 1924).

<sup>1</sup> The text of this treaty is printed in vol. 18 of the League of Nations Treaty Series.

*The Minorities Questions.*—The events and treaties shortly mentioned above delimited and to some extent guaranteed Poland's frontiers, although their security left much to be wished in view of the agitation conducted by her neighbours, especially Soviet Russia. It left her, however, with national minorities amounting to 9,000,000 out of a total population of some 27,000,000 (according to the Polish *Handbook*, 1925, 3,883,000 Ruthenians, 2,123,000 Jews, 1,057,000 White Ruthenians, 1,036,000 Germans, 72,000 Lithuanians and 210,000 Russians, Czechs, Tatars, etc.), sufficient, under the system of proportional representation and *scrutin de liste*, to give the bloc of national minorities 89 deputies in the first regular Sejm of 444 deputies.

The Polish-Minorities Treaty of June 28 1919 secured to all inhabitants of Poland full protection of life and liberty; it secured that all *bona fide* inhabitants of the districts allotted to Poland be admitted to Polish nationality and citizenship in the fullest sense (except in the case of recent German colonists); guaranteed the minorities the right to use their own language, to maintain their own institutions, to receive primary instruction in their own language, and where the proportion was considerable to receive "an equitable share in the enjoyment and application of public funds." The Jews are included among the "racial, religious or linguistic minorities"; Yiddish is recognised as a language, and the Jews are granted special protection as regards education and the keeping of the Sabbath, but are not recognised as "a separate political community within the Polish State." The guarantee for the execution of this treaty was entrusted to the League of Nations.

The most difficult minorities questions, after the Jews, proved to be those of the Ukrainians. East Galicia was not incorporated within Poland for a considerable period, during which, however, Poland treated it as an integral part of the Polish State. Complaints were numerous, and only grew less after the fate of the district had been decided because they were now unlikely to be heard. On Sept. 26 1922 the Sejm passed a general law on provincial self-government which established local bodies (*Dietines*) for dealing with purely local affairs. This law granted a small measure of autonomy to East Galicia, but not enough to prevent complaints; more particularly as the break-up of large estates under the Land Reform Acts was utilised to settle Polish peasants in the non-Polish districts.

Serious disputes arose, not only with the Ukrainians, but also with the German minorities. In 1924 a more conciliatory spirit began to prevail. On July 10 of that year a bill was passed providing for the use of Ukrainian, White Russian and Lithuanian in government offices, law courts and schools in districts where the majority of the population speaks one of those languages. The provisions were not extended to the Yiddish language. M. Thugut, the vice-premier in 1924, however, made persevering efforts to reconcile the minorities. In the summer of 1924 the Government concluded a kind of pact with the Jewish leaders by which the Government promised to promote in every way the religious and educational interests of the Jewish community, while the Jewish leaders pledged themselves to respect the integrity of Poland and to give loyal support to the Polish national Government.

Nevertheless, the racial and especially the religious enthusiasms of the Polish people were such that considerable friction persisted between them and the minorities. The latter were strong enough to form a serious danger to the Polish State in times of unrest, particularly along Poland's eastern frontier, where such unrest was actively fomented by the Soviet Government. This was perhaps the principal reason why relations between Poland and Russia continued unsatisfactory, consisting, indeed, mainly of a continuous series of "incidents" accompanied by mutual insults and threats of an appeal to arms.

*Internal Conditions, 1919-24.*—For the first years of its existence the history of Poland was dominated by its foreign political situation. Large parts of its area were the theatre of wars; its army absorbed a considerable proportion of its man-power; and military expenses were the main item in its budget. Nor was this purely due to aggressive or imperialistic tendencies. Poland's long and defenceless frontier necessitated the upkeep of a large army, more particularly when her chief neighbour was so unrelenting a one as Soviet Russia. Taxation was insufficient to meet these expenses, and Polish national resources—forests, oil-fields, etc.—were heavily mortgaged to foreign capitalists, generally French, in consequence.

The first period of Poland's independent existence bore the marks of its origin, which had been to some extent revolutionary, and during that period much advanced legislation was passed. Whereas the population up to 1918 had enjoyed little political liberty, the franchise system promulgated on Nov. 30 1918 for

the elections to the Constituent Sejm allowed the often untold wishes of almost the entire adult population of Poland to find expression. The Constituent Sejm was therefore mainly composed of peasants (who form 65% of the population of Poland), while the workmen were also strongly represented. These groups, however, and especially those of the peasants, suffered from a grievous lack of unity.

*The Agrarian Question.*—Not only were there antagonisms between the representatives from the three portions of the Republic, but their economic status and development were very different. In the west and the east of the country there were numerous large estates; but in the former districts the peasants were well organised and educated, while in the latter they were illiterate and backward. In Galicia there were numerous small estates, especially in the west; in Congress Poland the land reform commenced in 1905 had established a considerable number of small estates, but the reform was still far from completion. In both Galicia and Russian Poland there was a large landless proletariat, and in Galicia especially there were a great many dwarf holdings which were inadequate to support the families cultivating them. The natural desire of the peasants for a reform was increased by the example of events in Russia, and the first agitation contemplated a redistribution of a very radical nature; more especially as large parts of Poland were practically famine areas, and were only partially saved from the most widespread distress by the administration of relief (mainly granted by the American Food Mission) on a large scale.

The land reform bill was introduced in the Sejm on July 10 1919, and was passed by a single vote in a House of about 360. It proposed the nationalisation of forests and limited the amount of land to be held by an individual in Poland to from 148 to 248 ac., although in the non-Polish lands a higher limit of 988 ac. was fixed. The land thus available was to be used for increasing "dwarf holdings" to economic small holdings and settling the landless in new small holdings. The reform, however, was not carried through as originally intended. It was impossible in any case to put through expropriation on a large scale, for financial reasons. The bill became a convenient asset in the political bargainings of the over-numerous parties of the Sejm. It at last became law at the end of 1925. It now provided for the distribution of about 50,000 ac. a year to a period of 10 years. The maximum which an owner could retain was 148 ac. in the industrial centres, 740 ac. in the border provinces and 435 ac. in other areas. The benefit of the reform was largely enjoyed by the large and medium farmers, who thus came to form a conservative class. In general, however, owing to a series of remarkably good harvests, the agitation for reform largely died away.

*The Labour Question.*—The workmen in Poland were less fortunate. The industrial boom which almost all Europe enjoyed after the War missed Poland, where so many of the industrial areas had been ravaged and industry disorganised beyond the possibility of speedy repair. The closing of the Russian frontier, moreover, cut off Congress Poland's accustomed and almost sole market. In Galicia, Prussian Poland and Congress Poland, the labour legislation in existence in 1918 was extremely various, while in the last-named area it was very backward. No trade unions, in the modern sense of the word, existed in this, the chief industrial district of Poland; they had been prohibited by the Russian Govt., and the prohibition had been strictly enforced. The Socialist movement in these districts had therefore been of a radical and secret character, while the high proportion of Jews in Polish industry, as employers and workers alike, perhaps accentuated these traits, and certainly diminished the sympathy felt for the movement outside its own ranks.

The period during which Socialism was able actively to influence Polish legislation was short, but while it lasted some important measures were passed. Labour inspection was introduced on Jan. 3 1919, the organisation of the Labour Inspection Bureaux being slowly extended until the whole country was covered in 1923. The duties of labour inspectors include that of arbitration. Working hours were regulated by the Statute of Dec. 8 1919, by an amendment to this statute of Feb. 14 1922 and by various other statutes. The working day, with certain exceptions, is limited to eight hours and the working week to 46 hours. The Decree of Feb. 8 1919 introduced the freedom of coalition and defined the status of trade unions, which after that date grew rapidly in numbers and importance. At a later period, Poland took a very important part in the work of the International Labour Organisation, being among the States to ratify most readily the draft conventions prepared by that office.

Nevertheless, the position of the workmen in the republic was not happy. They were a minority, and their interests conflicted too often with those of the majority. During the period of the Russo-Polish hostilities in 1919-20 their sympathies were often deeply estranged from their country. The Communist element was large, and was actively encouraged by Russian agents, whose activities—carried on in defiance of the provisions of the Treaty of Riga—caused much ill feeling between Poland and Russia. Fear of Bolshevism caused the middle class and peasant parties to adopt an excessive severity towards any socialist organisations. Labour troubles were frequent, and often very grave. They abated when conditions grew more settled and communications improved. One relic of the early socialist influence was the over-staffing of industry and of public services, introduced as a palliative against unemployment; this over-staffing helped to burden the State exchequer and prolong the financial crisis.

*Administration and Finance.*—A capable civil service might have carried the country through without grave difficulties until conditions had settled down. Unfortunately, the only trained bureaucracy was that of Galicia, and this was not only numerically insufficient to meet the needs of the whole country, but had inherited by no means ideal traditions. The requisite staffs for the ministries were hastily improvised, but as a rule made up in quantity what they lacked in quality. They necessarily acquired experience slowly, and the first years of their administration were inefficient and expensive. Local Government had, indeed, existed before the War, but varied widely in the different parts of Poland. In Prussian Poland the rural commune had usually consisted of no more than 350 persons; in Galicia of about 1,000; and in Russia of some 7,000. District self-government did not exist in Russian Poland before the War. A large apparatus had thus to be improvised, and what was already in existence had to be made uniform. The efforts to introduce a uniform system of administration, as well as a uniform code of justice, largely occupied the first years of Poland's independence, and had not been wholly completed by 1925. These difficult tasks had meanwhile to be accomplished under the worst possible financial conditions. In 1919 the financial situation was chaotic. From 1921 on, Polish agriculture began to recover, and the peasants, the majority of the population, achieved a certain prosperity. The recovery of industry was slower; that of public finance slower still. Until M. Grabski undertook his reforms in Dec. 1923 the whole of Polish life was really dominated by the steady and sometimes extremely rapid fall of the mark, with the familiar accompaniments of inflation; the impoverishment of the middle classes and officials, antagonism between town and country, wage disputes in industry, and uncertainty as to the future.

*Parliamentary History.*—These difficulties were partly a cause, partly an effect, of an extraordinary political instability. Starting life as a country divided both politically and geographically, Poland achieved a great number of political parties. The Constituent Sejm had 13 political parties, as well as two independent members, and it was difficult to ensure a stable Government, especially as the Constitution gave Parliament a preponderating influence in the Government of the country. M. Paderewski resigned in Nov. 1919, following the decision of the Powers to grant East Galicia autonomy. A new Cabinet of the Right and the Conservative peasants was formed on Dec. 13 1919 under M. Skulski. Its most important member was M. Grabski, the Minister of Finance, who succeeded M. Bilinski, a high financial authority from the old Austro-Hungarian service. Grabski, a National Democrat, aroused intense indignation in Galicia by fixing the value of the krone, for exchange purposes, at some 20% below its market value. In May 1920 the Cabinet proposed to requisition the next harvest. Witos, the Galician peasant leader, caused a crisis by his opposition. As Witos himself was unable to form a Cabinet, Grabski formed a non-party Conservative Govt., with Prince Sapieha as Minister of Foreign Affairs. At the height of the Russian offensive in July Grabski resigned and Witos became Premier, introducing

Daszynski, the Socialist leader, as Vice-Premier for the purpose of negotiations with Russia. In July 1921 the Socialists and National Democrats left the Government, which carried on as a Government of the Left Centre. On March 17 the Constitution was adopted (*see below*).

In Aug. Witos was violently attacked by the Right in connection with the Upper Silesian dispute, and resigned. A non-party Cabinet under M. Ponikowski was formed on Sept. 27. The most remarkable member was M. Skirmunt, Minister of Foreign Affairs, who had been appointed to that post shortly before, on the resignation of Prince Sapieha. The Minister of Finance, M. Michalski, introduced a capital levy which stabilised the currency for a while. On March 3 1922 Ponikowski resigned owing to difficulties in the Vilna dispute. On March 27 he formed a second Cabinet, but resigned on June 2 owing to a difference of opinion with Pilsudski, who considered that the attitude of the Polish delegation at the Conference of Genoa had been too conciliatory towards Russia. The fall of Ponikowski, whose administration, unhampered by party conflict, had been a marked advance on those preceding it, both in foreign and financial policy, was the signal for an outbreak of party strife between Right and Left. After a prolonged crisis, during which Pilsudski came into hot conflict with the Right, who had selected Korfanty, of Silesian fame, as their leader, a non-party Cabinet under Nowak was formed on July 27. The electoral law was passed on July 28, and the general elections fixed for Nov. 5 for the Sejm and Nov. 12 for the Senate.

The elections to the Sejm returned 163 members of the Right, six of the Centre, 190 of the Left (41 Socialists, the remainder mostly small peasants), 83 of the National Minorities and two Communists. In the Senate the Right had 52 Deputies out of 111, the National Minorities 21; the other parties were small.

The first business of the two Houses was to elect a President. Marshal Pilsudski refused to stand. The parties of the Left, supported by the National Minorities and the Witos Peasant party, put forward and secured the election of M. Naturowicz, a friend of M. Pilsudski, who had acted as Minister of Foreign Affairs in several Cabinets. The defeated candidate of the Right was Count Zamoyski. Polish nationalism was infuriated by the election of a President through the votes of the National Minorities, including the Jews; and on Dec. 16 a fanatic (apparently of unsound mind) assassinated the new president. This act sobered public opinion. The new president was M. Wojciechowski, an old member of the Polish Socialist party and later a leader in the co-operative movement. Gen. Sikorski became Premier.

*Financial Collapse and Reforms.*—Poland's position in the early part of 1923 was still very unsettled. General uneasiness was felt as to how far the French occupation of the Ruhr, with its possible complications, might affect her position. The visit of Marshal Foch to Warsaw in the summer aroused a fear that Poland might be committing herself to secret military alliance; the French loan of 400,000,000 francs for purchase of material of war in France was regarded with suspicion as pointing in the same direction. The Polish mark was affected by the collapse of the German currency, falling in sympathy with it. M. Grabski was unable to put through the reforms which he desired, and the other Ministers of Finance proved quite unequal to the situation. Relations with Russia remained unsatisfactory, being especially troubled by the Soviet's persecution of Catholic priests. In the spring Witos secured a promise from the Right of more speedy execution of the land reform, and he became Premier on May 27 in alliance with the National Democrats.

The Left and the National Minorities showed considerable discontent, which was shared by Pilsudski, who had now been succeeded as Chief of the General Staff by Gen. Haller. Interest centered in the financial question; the mark sank in the autumn to nearly 1,000,000 to the pound sterling. There was serious industrial unrest in July and again in Oct.; but fortunately the harvests were again excellent. On Oct. 27 the Government took in two strong personalities from the Right, M. Korfanty and

M. Dmowski; but the finances were not reformed, the peasant parties were discontented, and the Government resigned on Dec. 11. On Dec. 19 a non-party Government was formed under M. Grabski, Poland's most able finance minister. The political parties agreed to subordinate all other problems to those of financial reconstruction. M. Grabski, who had received valuable advice from a British financial mission under Mr. Hilton Young, asked for emergency powers, which were granted him on Jan. 3 1924. He was now able in an astonishingly short time to stabilise the currency and balance the budget and the financial problem occupied the chief attention of the country throughout 1924.

The consolidation of the Polish debt to America (Nov. 14 1924) and to Great Britain (Dec. 10 1924) marked a political as well as a financial advance. A commercial treaty with Great Britain had already been concluded (Nov. 26 1923) and one with the United States was concluded provisionally on Feb. 10 1925. Among other agreements concluded by Poland may be mentioned a commercial treaty (May 12 1922), a special commercial agreement (Jan. 21 1923) and an emigration convention (May 1924) with Italy; a convention regarding option and nationality with Germany (Aug. 30 1924).

*The Polish Concordat.*—An agreement of great interest was the Concordat reached with the Holy See on Feb. 10 1925. It should be remembered that Pope Pius XI. before his ascension of the Holy See, had been Papal Nuncio in Poland. The Concordat differs materially from any other similar arrangement. The Catholic Church is granted an absolute freedom of execution of her authority and jurisdiction in Poland; the assistance and support of the State being assured her in this respect. The States' interests in connection with nominations for the higher ecclesiastical posts are adequately protected. In religious education, the competencies of Church and State are exactly defined. The division of Poland into ecclesiastical provinces is carried out in such a way that no portion of Polish territory remains subject to the jurisdiction of a bishop residing outside the borders of the State. In this connection must be mentioned the establishment of an autocephalic Orthodox church in Poland, which received the blessing of the Synod and of the Oecumenical Patriarchate in Constantinople on Nov. 11 1924. The political importance of the religious question in Poland can hardly be over-estimated. Religious differences have always been far more important than racial in dividing Poles and Russians, Poles and Ruthenes, Poles and Jews, and even Poles and Germans. It was largely owing to the religious bond with clerical circles in Vienna that the lot of Galician Poles in Austria was happy. To some extent Catholic Poland to-day has entered into the succession of the Holy Roman Empire and the Catholic interest is one of her chief supports in her struggle with Russia.

*The Problem of Security.*—Meanwhile the question of security, in all its forms of guarantee of security, arbitration and limitation of armaments was beginning to succeed that of reparations as the chief European problem, and Poland, whose interest in the latter question had been secondary, found herself one of the parties most directly concerned in the deliberations of the Powers and of the League of Nations. Simultaneously, her position with regard to the League changed. The 29th session of the Council of the League (June 17 1924) was the first at which there was no Polish question on the agenda of the meeting; hitherto Poland had only too regularly occupied the attention of the representatives of the Powers as plaintiff or defendant in wearisome frontier disputes.

Count Skrzynski, who became Poland's Foreign Minister for the second time in Aug. 1924, took an active part in the work of the Fifth Assembly of the League (Sept. 1924). The Polish delegation maintained that the performance of a mutual guarantee pact, which would facilitate the application of Articles 10 and 16 of the Covenant, could alone secure disarmament in accordance with Article 16; and spared no effort to co-ordinate the opposing views and to assist in the drafting of the Geneva Protocol. The Protocol, which embodied all three aspects of the problem of security, was in complete agreement with the Polish thesis.

The rejection of the Geneva Protocol by Great Britain in 1925 alarmed Polish opinion. The original German proposals made to France in the spring of 1925 treated the problems of Germany's western and eastern frontiers separately. In Poland it was feared that a system of regional pacts by which Germany guaranteed her western frontier alone might endanger the integ-

rity of Poland's western frontier. Poland contended that the question of security in Western Europe was inseparably connected with that of the stability of frontiers in the East, and that the conclusion of agreements guaranteeing Germany's western frontiers could not in any case create a state of uncertainty in respect of her Eastern frontiers, as both were established by the Treaty of Versailles and any new agreements would have to be in strict accordance with the Peace Treaties and with the existing alliances. In March the Sejm passed a resolution protesting against any tampering with Poland's frontiers. The Slav minorities did not join this protest, although expressing themselves in favour of Poland's present western frontier. They were clearly living in hopes that the question of East Galicia would be reopened at some future date.

Poland's relations with Germany were farther troubled, firstly by the breakdown of negotiations for a commercial treaty, followed by a tariff war, secondly by a failure of the arrangements to receive the German natives of Poland who had not opted for Polish nationality, whom the Polish Govt. called upon to leave Poland on or before July 31 1925. The question of Danzig, moreover, was a perennial cause of friction. Its economic importance for Poland, its racial and historical bonds with Germany, were never forgotten by either party. These considerations, as well as the continued friction with Russia, were a prime factor in drawing Poland and Czechoslovakia closer together. On May 6 1924 a Polish-Czechoslovak conference in Cracow had finally regulated the Jaworzna dispute; and on April 23 1925 the two countries signed a treaty of arbitration, a commercial treaty and an agreement which settled certain outstanding points of dispute. Although Poland still remained outside the Little Entente, the position of the Slav bloc along Germany's eastern frontier was greatly strengthened, and it was obvious that in future the countries composing this bloc would act in greater accord than previously.

The Locarno pact (*see SECURITY*) signed on Dec. 1 1925 brought forward a fresh solution to the problem of Poland's security. Poland and Germany signed an arbitration treaty which included in its preamble the recognition of the inviolability of the existing treaties, the recognition of the integrity of each contracting party's rights, and the elimination of war as a means of settlement of disputes and conflicts. In a separate treaty of guarantee between France and Poland, France is referred to as the guarantor of the Polish-German arbitration agreement. France undertook in the case of an unprovoked attack by Germany against Poland to abandon no means of assistance at her disposal and within the limits of the Covenant and of the political agreements with Poland.<sup>1</sup>

Polish opinion was not easily reconciled to the idea of the Locarno pact. The arrangements were accepted, but there was some feeling that Poland was being abandoned by France which even brought about a temporary rapprochement with Soviet Russia. M. Chicherin, the Russian Commissar for Foreign Affairs, visited Warsaw Sept. 26-30 1925, but the visit did not, apparently, result in any concrete revision of the policy of either country. At the same time, Poland was unfortunate in losing

<sup>1</sup> A project for disarmament submitted to the Conference of Poland and the Baltic States held in Moscow on Nov. 30 1922 had already been rejected by these States on the ground that the plan, if adopted would secure Russia a military predominance without providing adequate political or moral guarantees to the other contracting parties. On this occasion the absence of Russia from the Conference created a great difficulty, as the acceptance of the decisions of the Conference by Russia's neighbours would place them at an obvious disadvantage towards Russia who remained free from any international obligations. The Polish delegation accordingly brought forward a clause, which was adopted, exempting the countries referred to from the duty of registering and publishing figures concerning their traffic in arms until Russia had signified her access to the Convention. A further protocol brought forward by the Polish delegation, condemning chemical and bacteriological warfare, was also adopted by the Conference. At a conference held at Riga (July 9-11 1923) the four Baltic States (not including Russia) agreed to support disarmament proposals at Genoa if accompanied by a general treaty of neutral guarantee.

M. Grabski, who resigned on Nov. 13 in consequence of a disagreement with the Bank of Poland. The zloty fell to an alarming degree, and it seemed clear that Poland's financial troubles were, after all, not over. On Nov. 20 M. Skrzynski formed a new coalition Cabinet, but was obliged to admit that the financial and economic state of the country was serious, the treasury was almost empty, the shortage of private capital was very great, and unemployment was increasing rapidly.

The year 1926 opened amid considerable friction between the Right and the Left. The coalition Government maintained itself throughout the winter, but the steady fall of the zloty aroused great dissatisfaction, and controversy arose as to who should bear the brunt of the retrenchments which were obviously indispensable. The Socialists demanded a large programme of public works to relieve unemployment, and a rise in salaries for the lower branches of the civil service, while refusing to admit a reduction in the number of railway employees. They proposed to make their economies on the army budget. The Right desired a reduction of civilian expenditure, while maintaining the army at full strength. This dispute affected the whole life of the country. The Left rallied round Marshal Pilsudski who was still a popular hero in his retirement, and he opened a series of devastating criticisms on the army, its conduct and its influence on national policy.

There was a fresh frontier "affair" with Lithuania in March, which followed closely on a more serious incident in which Germany was concerned, a large German espionage organisation in Poland being discovered. Public opinion in Poland grew more excited and alarmed than ever. On March 2 the Seym ratified the Locarno Treaties, but there was a strong feeling that the security which they afforded Poland was inadequate. This feeling found expression when the League of Nations met later in the month to elect Germany a permanent member of the Council and put the Locarno pact into operation. The Polish delegates insisted on Poland's right to a permanent seat on the Council. They afterwards withdrew their claim, but other countries made similar demands, and the admission of Germany had to be postponed.

There were signs after this that Poland was working to form an Eastern European bloc in conjunction with the Little Entente and possibly Italy. The treaty with Rumania was renewed on March 26 in the altered form of a guarantee pact, each party guaranteeing the political independence and territorial integrity of the other and pledging itself to immediate aid and assistance in case of unprovoked aggression.<sup>1</sup> On April 14 Count Skrzynski, on a visit to Prague, signed an arbitration treaty with Czechoslovakia, the details of which were kept secret, but which was stated by Dr. Benesh to be "much more than an arbitration treaty . . . an expressive symbol of definite politics," while Count Skrzynski declared that "here in Central Europe a Slav bloc has been created." Secondly, a treaty of ratification was signed, which cleared away certain outstanding points of disagreement. From Prague Count Skrzynski proceeded to Vienna, where a new treaty of arbitration was signed (April 15 1926) between Poland and Austria.

*Marshal Pilsudski's Coup d'état.*—Meanwhile, however, internal dissensions had become acute while the news of the conclusion of the second Russo-German treaty (see GERMANY) increased the general nervousness. Gen. Szepticki, chief of the army inspectorate at Cracow, whom Marshal Pilsudski had been attacking with particular vehemence, resigned his post, publishing his reasons for doing so. The adherents and opponents of Pilsudski now formed two definite, opposing camps in the army. The quarrel between the Marshal and the Parties of the Right was of no new date. It was largely owing to fear of Pilsudski's possible excessive influence that the Polish Constitution had been framed to allow the legislature an excessive power by comparison with the executive. Pilsudski had since been gradually edged out of power, and was now in retirement

pending his appointment as inspector-general and commander-in-chief in time of war. The Right, however, desired to frame the bill containing this appointment in such a way as to bring the army under the direct control of Parliament, while Pilsudski insisted on independence from the Ministry of War. At the same time the discussions on the budget commenced. The Minister of Finance proved unable to reconcile the opposing claims of the Right and the Left. The Socialist ministers of the Cabinet resigned; on April 21 Count Skrzynski himself resigned in consequence. At the request of the President, Skrzynski resumed power with a rump Cabinet of the Right to pass the monthly budget. Three fruitless weeks were passed in the endeavour to form a reasonable parliamentary majority, till on May 11 M. Witos, the peasant leader, succeeded in forming a ministry.

This solution evoked considerable dissatisfaction. Both sides were weary of the futile parliamentary struggle, and it was rumoured that M. Witos proposed to cut the knot by establishing a dictatorship of the Right, supported by the Polish nationalist circles and Fascist organisations. Above all, Witos proposed to pass through the disputed Army bill, for which Count Skrzynski had been unwilling to assume responsibility. On May 12 Pilsudski, whose following was growing from day to day, suddenly attacked Warsaw at the head of the troops which espoused his cause. The Government prepared to resist, proclaimed Pilsudski a rebel, and summoned its own adherents in the army to Warsaw. Throughout May 13 and 14 there was heavy fighting in the streets of Warsaw, in which at least 200 persons appear to have lost their lives. On May 14 the Social Democratic party proclaimed the general strike in Warsaw and certain other Polish towns. The Government's troops were unable to come up, and by May 15 Pilsudski won a definite victory. The Government and the President of the Republic resigned, and M. Rataj, Marshal of the Seym, became acting head of the State, in accordance with the terms of the Polish constitution. A non-party Cabinet was formed, pending the election of a new President. The troops which had supported M. Witos returned to their garrison, and by May 17 most of the country was quiet. The new Government proclaimed "the moral regeneration of the nation" as against "individual and party sectionalism." Pilsudski was elected President but at the beginning of June 1926 refused the office in favour of his nominee, Professor Ignacz Mosiecki. He remained, however, the dictator of the country. (J. GRA.)

#### CONSTITUTION

Poland is a Republic. The legislative power is vested in a diet (Seym) and a senate, which are summoned, adjourned and dissolved, but not without their own consent, by the President. The Diet is composed of paid members elected for five years, upon a system of proportional representation. Suffrage is universal, all who enjoy full civic rights and who are over 21 being qualified to vote, but, since voting is personal, soldiers on active service are excluded. Citizens over 25 are eligible for election to the Diet; members of the civil service cannot be elected for the district in which they hold office. The minimum age for voting in senatorial elections is 30, whilst no one under 40 is eligible for election.

Bills go to the Senate after being passed by the Diet and if no objection is raised within 30 days the bill becomes law. Amendments suggested by the Senate are considered and voted on by the Diet, which can override them by a majority of eleven-twentieths. The budget is fixed each year for the following year; taxes and customs duties can be established only by law and a supreme court of control superintends the management of state finance.

The executive power is exercised by the President and a Council of Ministers who are responsible for his official actions. He is elected for seven years by the National Assembly, that is, the Diet and Senate acting together. Laws are to be signed by him and by the President of the Council and the Minister concerned. The President has the supreme power in the army, except in time of war, when the Minister for War is responsible for all military affairs. The President can declare war and make peace only with the consent of the Diet. He has the right of pardon.

<sup>1</sup> Rumania forms the centre of Polish interests in the Balkans, partly because of their common frontier with potential importance of Rumanian ports as an outlet for Polish trade.

For purposes of administration Poland is to be divided into palatinates, districts and urban and rural communes, these forming the units of local government. Economic autonomy is established by means of chambers of agriculture, commerce, industry, etc., which will together form the Supreme Economic Chamber of the Republic, the competence of which required further legislation. The control over the whole administration is vested in Administrative Courts headed by the Supreme Administrative Tribunal. Judges are nominated by the President, whilst justices of the peace are popularly elected. Judges can be removed from office only in certain legal cases and following a judicial decision. A united code for justice, both civil and criminal, had not been fully completed in 1924, and the Russian, German and Austrian codes, together with certain Polish regulations, were still in force in various parts of the country. All citizens are equal in the eyes of the law, protection of life, liberty and property being assured to all inhabitants. State protection is given to labour and insurance for unemployment, illness and accident is guaranteed. Roman Catholicism is the recognised religion of the country but others are allowed provided they are in accordance with the law.

Land must be cultivated from the point of view of public utility. The law is to decide to what extent citizens and independent associations may cultivate the land and exploit its mineral wealth, and in what cases the State may repurchase property to improve the value of its production.

(C. A. M.)

**BIBLIOGRAPHY.**—Dr. J. Grzymala-Grabowiecki of the Polish Foreign Office kindly supplied a detailed and valuable account of Poland's foreign relations since 1919, large portions of which are incorporated in the above article. Literature on modern Poland is extremely scanty. The following may be quoted: Prof. W. A. Phillips, *Poland* (Home University Library, N. D.); L. Bernhard, *Die Polenfrage* (Leipzig, 1910); J. Moraczewski, *Zarys sprawy polskiej w obecnej wojnie* (Lausanne, 1915); J. Rosner, *W krytycznej chwili* (Vienna, 1916); W. Feldman, *Geschichte der politischen Ideen in Polen* (Munich, 1917); I. Daszynski, *Cztery lata wojny* (Cracow, 1918); O. Czernin, *Im Weltkrieg* (Berlin, 1919); *Constitution de la République de Pologne du 17 mars 1921* (Warsaw, 1921); *Mémoire sur le traité de Riga* (Paris, 1921); B. Winiarski, *Les institutions politiques en Pologne au XIXe siècle* (Paris, 1921); A. Skrzyski, *Poland and Peace* (London, 1923); *The Polish Handbook, 1925* (London, 1925).

## II. DEFENCE

**Man-Power.**—Military service is obligatory for all male subjects of the Polish State between the ages of 21 and 50. On general mobilisation men of 19 and 20 are also liable. The terms of service are: in the active army, two years from 21 to 23; in the reserve, 17 years from 24 to 40; and for the *levée en masse*, 10 years from 41 to 50. Officers and other ranks on the reserve are called out from time to time for refresher training. There is no training for the *levée en masse*.

The annual class is calculated to produce an average of 160,000 conscripts, of whom about 110,000 are fit for general service. The total mobilisable man-power may be summarised as follows: permanent cadre, 50,000; two serving contingents, 220,000; reserves (men up to 40 years of age and men of 19 and 20 who are liable to be called up), 2,155,000; *levée en masse* (10 classes at an average of 80,000 each), 800,000; making a total of 3,225,000. From this total must be deducted all men who would be retained in civilian life on those works that are regarded as of national importance.

**Army Organisation.**—In peace time the army is organised into the following units: 30 divisions of infantry, of three regiments each; 4 divisions of cavalry, of three brigades of two regiments each; 5 independent cavalry brigades of three regiments each (one brigade has four regiments); 30 regiments of field artillery; 10 regiments of heavy field artillery; 10 divisions of horse artillery; 2 regiments of mountain artillery; 1 regiment of super-heavy artillery; 1 regiment and 10 independent batteries of anti-aircraft artillery; 4 companies of foot artillery; 1 tank regiment; 10 engineer regiments and 6 aviation regiments. There is the normal complement of army and divisional troops. The total establishment of the army is about 270,000 all ranks. In war it is estimated that Poland could mobilise and equip an army of about 1,000,000 men. Of these some 40% would be required for lines of communication troops and services, leaving a field army of 480,000 all ranks.

**Recruiting Organisation.**—Poland is divided into recruiting areas which are subdivided into recruiting districts. The civil authorities of each recruiting district keep a register, and summon each class annually to appear before a recruiting commission

which is a mixed civil and military board. Those passed fit for general service are posted to units but remain on leave until actually ordered to join, usually in Oct. of each year. In each recruiting area a revision commission is set up to deal with appeals against the decision of the recruiting commission in cases where grounds for appeal are shown to exist. Exemptions from service are granted in certain cases, e.g., on religious and compassionate grounds, etc.

**Administration.**—The country is divided into 10 administrative districts, each under a general officer commanding, who is responsible for the administration and mobilisation arrangements of his district. The 10 districts are grouped into five army inspectorates. Army inspectors are responsible under the Minister of War for the training and efficiency of the troops in their inspectorates. The headquarters of districts are as follows: Warsaw, Lublin, Grodno, Łódź, Cracow, Lwow (Lemberg), Poznań, Toruń, Brześć and Przemyśl. The headquarters of inspectorates are as follows: (1) Wilno (Vilna), No. 3 and 9 districts; (2) Warsaw, No. 1 and 10 districts; (3) Toruń, Nos. 7 and 8 districts; (4) Cracow, No. 4 and 5 districts and (5) Lwów, No. 2 and 6 districts.

**The Higher Command.**—The President of the Republic, as head of the executive, is the supreme chief of the army. He grants commissions, makes appointments to commands from divisional commanders upwards, awards promotion and confirms retirements. For other matters he delegates his authority to the Minister of War. The Great War Council is an advisory council on important military questions. It consists of the members of the Cabinet and the highest military authorities. It is summoned as required, and is presided over by the President of the Republic. The Small War Council sits permanently. It consists of the Minister of War, the army inspectors, the inspectors of artillery and cavalry, the chiefs and sub-chiefs of the general administrative staffs and other members co-opted for special business. It is the executive organ for the preparation of military operations; its decisions on these matters are obligatory on the Minister of War.

The Minister of War is the governing authority in all matters connected with the army, including training, armament, supply, recruiting, etc. Considerable powers are delegated to army inspectors and general officers commanding military districts, who thus act as the executive medium through which is carried out the policy laid down by the Minister of War. The Ministry is divided into three branches: General Staff, Administrative Branch and Army Control Branch (finance). A draft bill for the appointment of an inspector-general was under consideration in 1921. It is intended that this office shall carry the power of practically complete control over military affairs while remaining nominally responsible to the Minister of War. In time of war the inspector-general would become commander-in-chief. The general staff is organised in five bureaux: organisation, intelligence, instruction, communication, personnel.

**Armament.**—The armament of the army is not yet homogeneous, though a scheme for introducing similarity of weapons is being carried out gradually.

As regards rifles, the French Lebel, Austrian Mannlicher and German Mauser are in use. The latter is being adopted as the universal pattern and its manufacture has been started locally.

The light machine-guns are the French Chauchat, German Bergmann and the Lewis gun. These types are to be replaced by a Browning automatic rifle firing Mauser ammunition. The manufacture of this gun is to be undertaken in Poland. Heavy machine-guns in use are the Maxim, Hotchkiss and Schwarzlos. The Hotchkiss firing Mauser ammunition is to be generally adopted and manufactured locally. The field-gun is the French 75 mm.; the field howitzer, the 100 mm. Skoda. The horse-artillery gun is a 3-inch Russian field-gun, but it is proposed to reline this weapon to take the same ammunition as the 75 mm. gun. The mountain gun is the French 67 millimeter. The heavy field artillery is armed with a 105 mm. gun and the 155 mm. Schneider howitzer. The heaviest field artillery has a 120 mm. gun.

The cavalry is armed with sword and carbine, while the front rank of line troops carries a lance. The carbine is to be standardised to take Mauser ammunition.

*Frontier Guard.*—A somewhat novel body has been created in Poland called the Corps of Frontier Guards. The Corps is organised on a military footing and consists mainly of volunteers from the regular army, the establishments being completed by conscripts when necessary. Its strength is about 25,000 all ranks, organised in 6 brigades subdivided into battalions and squadrons. The headquarters are at Warsaw, and the units distributed along the whole length of the Lithuanian, Latvian and Soviet frontiers. Its duties are the protection of the country from armed raids and banditry, the prevention of smuggling and the closing of the frontier to unauthorised individuals, propaganda, etc.

*Navy.*—The navy also comes under the orders of the Minister of War. A special department exists in the Ministry supervised by an admiral with a staff of some 30 officers. The total establishment is 2,350 all ranks, of whom 570 are on a long service engagement. The sea-going fleet consists of a division of six torpedo boats; a training division of two gunboats and four mine-laying trawlers; a hydroplane division, and the naval port of Gdynia, including the land defences. A programme of naval expansion is under consideration, and will probably be put in hand as soon as the financial situation permits. The river fleet consists of the Vistula Flotilla and the Pinsk Flotilla; there are in all four monitors, six river gunboats, 25 motor boats and some other small craft.

*Air Force.*—The Polish air force is part of the army, and is under the Ministry of War, a special department being concerned solely with aviation. The strength of the air force is about 700 officers and N.C.O. pilots. The full establishment, which will not be reached before 1928, allows for 12 regiments of aviation with a total of 580 machines. At present six regiments only have been formed. In time of war the regimental organisation is abolished and divisions of aeroplanes are allotted to formations as required.

*Discipline and Morale.*—Discipline in the army is, generally speaking, good, relations between officers and men being on a satisfactory basis. The tendency of senior officers to dabble in politics and criticise each other in the Press is an adverse factor which should be eradicated in time. As regards morale, the strong points are the intense patriotism of the Poles and the increasing efforts of officers to study the men's welfare and provide recreation. On the other hand the army contains a considerable non-Polish element and barracks are often bad. On the whole the weak points are being attended to and morale is being steadily raised. The lower ranks work hard and apply themselves to learning.

*Tactical Efficiency.*—Since 1919 the army has had a large French military mission as instructors, with the result that there now exists a considerable number of well trained staff and regimental officers. The Polish Army compares well with any but the highest Western standards. The general obstacle to progress is the lack of money. Until the economic situation improves, the army must continue to suffer from shortage of material, curtailed programmes of training and inferior barrack accommodation. (A. P. W.)

### III. ECONOMIC AND FINANCIAL HISTORY

*Population and Resources.*—The area of Polish territory after the final determination of the frontiers is 149,895 sq. m., with a population numbered at 27,192,674 on Sept. 30 1921, and estimated at 28,896,000 on Jan. 1 1925. Sixty-five per cent of the population live on the land, and the wonderful soil, the vigour of the peasantry and the proximity of big industrial markets offer the certainty of prosperity on the condition of good management.

But the economic organisation of this territory by a political unit was kept in suspense after 1918 until some definite basis could be created both for external and internal relations. In foreign affairs the essential preliminary of defined frontiers was not obtained until the defeat of the Bolshevik armies in Aug.

1920 had been crowned by the peace of Riga (March 1921), and not put beyond question until Polish Upper Silesia was taken over in July 1922.

At home a constitution and administration had to be created in the midst of the war with the Bolsheviks and the damages of the World War repaired. Practically, Poland started her career nearly three years after her neighbours, handicapped by a scarcity of able men, a mediocre administration and the inherited hostility of her people to all governments.

*Agriculture, Forestry and Related Industries.*—The devastation and dislocation of the War delayed the recovery of agricultural production until 1922-3. In 1919 considerable quantities of cereals were imported. Even in 1920 the crops (except potatoes) averaged only about 30% of a good pre-War year. The industry and thrift of the Polish farmer brought about a progressive improvement by 1921-2. Imports of fertilisers, implements and machinery rapidly increased, the worst ravages of the War were repaired, and co-operative marketing made considerable progress. Both area under cultivation and yield per acre show a marked advance. The excellent harvest of 1923 enabled Poland to export cereals, out of crops which are given as:—

|                    | Production in Metric Tons | Area in Hectares |
|--------------------|---------------------------|------------------|
| Rye . . . . .      | 5,962,000 . . . . .       | 4,644,768        |
| Wheat . . . . .    | 1,354,000 . . . . .       | 1,017,365        |
| Barley . . . . .   | 1,656,000 . . . . .       | 1,199,457        |
| Oats . . . . .     | 3,522,000 . . . . .       | 2,515,076        |
| Potatoes . . . . . | 26,494,000 . . . . .      | 2,279,219        |
| Beet . . . . .     | 2,081,000 . . . . .       | 108,729          |

The most immediately advantageous crop has been sugar beet, exports rising from 40,000 tons of sugar in 1921-2 to 190,000 tons in 1924-5. This industry is highly organised, both in labour (the men work in the fields in the summer and in the factories in winter), in supplying and in marketing. At an early date it established connections in London and obtained credits, exporting sugar and importing fertilisers and machinery. It has steadily consolidated its reputation and increased its operations.

In 1919 some damage had been done to the forests by foreign Governments, machinery was lacking and in many areas the methods of exploitation were primitive. The chief difficulty was inadequate transport. The forests were nationalised in 1919. About one-third are worked by the State and the rest are State-controlled. Exports are chiefly and increasingly boards, sleepers and other half-finished articles.

*Mining and Metallurgy.*—Petroleum mining in Galicia had been encouraged by the Germans during the War, but the difficulties of production have increased as it is now necessary in many cases to sink wells to low levels. Petrol production is under Government control, intended to ensure cheap oil for the population, but disadvantageous to the mines. The Government's practice of paying for oil many months after it was piped caused serious financial and labour difficulties during the inflation period. Lack of capital for exploiting the deeper mines and restrictions on export have been additional causes of difficulty. Production remains round about half the pre-War level. Exports of petroleum products are growing at the expense of home consumption.

Other industries of importance, depending on minerals, are cement, glass and salt (Government-owned). Efforts are being made to develop the construction of locomotives, aeroplanes and machines of all kinds, largely by customs protection aimed at increasing Poland's metallurgical development for both economic and military motives. These efforts have met with but moderate success.

The coal-mines of Dombrowa, Cracow and Teschen were favoured from the beginning by the Polish Govt., which facilitated the renovation of damaged plant and purchase of new equipment. The mines had an abundant supply of inexpensive labour, and thus made rapid progress. It is claimed that their output had passed the pre-War level by the end of 1922. The Upper Silesian area, added in that year, surpasses the rest in

area and quality. Poland now ranks after Germany and Great Britain as the third coal-producing country of Europe. Lignite is of little importance. The Ruhr occupation increased the German demand for Polish coal in 1923, but in 1924 the "stabilisation crisis" and the world-wide shrinkage in the demand for coal began to restrict production, which by the middle of 1925 had fallen to about 75% of the pre-War figures.

*Industry.*—Apart from the industries already mentioned, and the important textile manufactures, the industries are not large and work chiefly for the home market. There is a general shortage of both working and fixed capital, due to a century of poverty and foreign exploitation, to the financial troubles of the last few years, and to the inability of Poland to attract foreign capital in large amounts. Labour, more particularly clerical labour, is not of very high quality. The bulk of the clerks still count on the *abacus*. The reserve of skilled artisans capable of producing highly finished articles is small. As the industries produce little for export they are dependent on the home market, where the standard of living of the bulk of the population is low and the demand liable to fluctuation according to the harvests.

The textile industries are distinguished from other Polish manufactures by their size, and by the vigour and ability of their leadership. In 1919 the mills found themselves despoiled of the great bulk of their machinery, equipment and raw materials, in debt for pre-War supplies, and deprived of the Russian market which had taken 75% of their output before 1914. Making arrangements for their pre-War debts, they were able to obtain certain credits for the purchase of machinery and cotton. Wool came from the British Govt., financed out of relief credits. The remaining machinery was reassembled, and manufacture was thus able to make an early start. It found a great demand in the home market, depleted by eight years of war, and made rapid progress. Russia, officially closed, took fair quantities surreptitiously. Other foreign markets, notably Rumania, presented themselves. By 1921 production of cotton stood at 60% of the pre-War figure, and by the end of 1922 the pre-War figure was passed. In the home market Łódź sold at prices generally above the level of prices abroad (partly to provide insurance against depreciation of currency). From an early date the textile industry had direct access to the state bank for its credits, and individual firms were thus able to protect themselves to some extent against fluctuations of the exchanges. In the last stages of inflation in 1923 considerable depression set in, and this was intensified by the financial reform of 1924. Foreign credits revived the cotton and woollen industries in the autumn of that year, but the acute credit crisis of 1925 brought the industries into difficulties.

*Communications.*—From her own resources Poland could do little to equip her railways, as the repairing shops in the Russian provinces were almost completely destroyed. Her greatest deficiency—rolling stock—was largely made good by considerable allocations from Germany and Austria. A large quantity still had to be purchased abroad; repairing works had to be constructed, shunting stations installed. Works for manufacturing locomotives and railway coaches were created, and the immense damage in the eastern districts to bridges, stations, warehouses, etc., has been made good in large measure. The former Russian lines have been adapted to the narrower gauge.

The greatest technical problem was the adaptation to the new directions of trade. From being strategic lines and channels of exploitation leading to St. Petersburg, Vienna and the German centres, the systems had now to provide abundant communication with Danzig and (later) Upper Silesia. Equally serious were the difficulties of administration—first in replacing the German employees in the former German areas, and then the more enduring difficulty of training a personnel. The superabundance of untrained hands introduced, under Socialist influence, the eight-hour day, the special passes for Government employees augmented at the same time the working difficulties and the deficit. But great and rapid progress was made. The American railway mission gave valuable advice, and enabled Poland to avoid many of the mistakes made by other European countries. By the end of 1923 the technical condition of the railways would compare most favourably with that of almost any European system. But the charges, in consequence of depreciation of the mark, were too low, and the deficit on the railways was one of the chief causes of the deficit in the budget. Early in 1924 the railways were made autonomous. A gold loan, guaranteed

on the receipts of the Galician railways, provided them with some working capital. Fares and rates were increased, and economies on the administration finally enabled the railways to show a surplus even in 1924, which has been maintained.

The long and numerous waterways are the natural means of transport for much of Polish traffic, but repairs to the banks, dredging and other work is sorely needed. Capital and organisation have been lacking, however, and little has been done.

*Labour and Social Questions.*—Social questions in Poland cannot be measured by the standards applied in countries further west. The differences in the standards of life and in the habits of the people (e.g., in the part played by religion) makes statistics peculiarly hard to interpret. This is notably the case for figures of industrial unemployment. Most of the 30% of the population who are not employed in or about agriculture still retain family connections with the land and are accustomed to return there in any time of stress. In consequence there is an unusual "elasticity of supply" in Polish industrial labour. Since the War this situation is seriously complicated by the great increase of the population. Poland is now deprived of her two great *débouchés*—the United States, which absorbed 100,000 workers yearly; and German agriculture, which took as many as 1,000,000 persons in the season. The population has been increased by expulsions from Russia, whilst the rate of annual growth is perhaps the highest in Europe.

Under Socialist influence, room has been found for much unskilled labour in the railways and other Government services, thereby hampering the efficiency of these young administrations and increasing the deficit in the state budget. Trade union policy has maintained the extremely large number of public holidays, extended the practice of the eight-hour day, and increased the number of men on the pay-roll of industry. The ability of Polish industry to compete with foreign, and especially German, industry has been very much restricted, and Polish finances have suffered. Other factors depress the standard of comfort, notably the housing shortage, which with Poland's expanding population is perhaps more intense than anywhere in Europe. The repair of about 60% of the War damage has done something to relieve the agricultural areas (until 1921 hundreds of thousands of people lived in holes in the ground), but in the towns no family may by law retain for its own use more rooms than its own number plus one.

As a political force Communism is spent, killed by Polish patriotism and the Bolshevik war. But Socialism of the Marxian type is important both in politics and in trade unionism. In the latter it has combined with economic forces to restrict output and promote unrest and strikes, which have been very frequent. In 1925, however, in many industries, notably in Upper Silesia, under the stress of "stabilisation" and German competition, the hours and efficiency of labour have been increased. A number of statutes for the protection of the workers against accident, illness, old age and unemployment have been passed. In this, as in some other fields, there is a difference between Polish law and Polish practice.

Trade in Poland is conspicuous for the large proportion of middlemen, some of whom fulfil no economic purpose. Of them a large number are Jews, who form 10% of the populace of Poland and 30% in Warsaw. They arouse much popular prejudice, and are one of many causes which give to economic and social affairs a more emotional and less calculable quality than is common further west.

*Foreign Trade Relations.*—The political framework of Poland's foreign trade has been but recently shaped and is not yet complete. Though commercial agreements with Czechoslovakia and Rumania were made in 1921, and with Austria, Yugoslavia, Switzerland, France, Italy and Japan in 1922, this list excludes both Poland's chief customer and her largest neighbour, and the agreements themselves were of a primitive kind. During the period of inflation, prohibitions both of export and import were common, but with the stabilisation of the currency and some years of experience the way was open for the introduction of a new customs tariff which was instituted in 1924. In it the needs of the national finances, which had hitherto been almost

completely neglected, also obtained some recognition, although in a country so predominantly agricultural as Poland the customs duties must be one of the foundations of the national revenue. Poland suffers from exceptional difficulties in the administration of her customs revenue, due to the length of her frontiers and their lack of natural protection. Danzig is now included in the Polish customs tariff and organisation. The attempts to make a commercial agreement with Germany led in 1925 to profound disagreement, the reimposition of the system of prohibitions and an overturning of Poland's trade balance.

Too much reliance cannot be placed on statistics of foreign trade, especially during the inflation period. The years 1920-1 were disastrous ones. Devastation, disorganisation and the Bolshevik war reduced exports to perhaps 10% of the value of imports, which included large amounts of American grain financed by the Allies out of relief credits. By 1922 the worst was over. By June of that year, excluding trade with Russia and through Danzig, exports were estimated at 50% of imports, and in 1923 that exports of commodities probably equalled imports in value, while the total foreign trade increased by a fair amount. In addition, considerable sums were received annually in remittances from Poles in America and small amounts from Poles working in the devastated regions of France, the total probably averaging about \$32,000,000 per annum, or 12% of the total imports.

Political changes have not greatly affected the main currents of Poland's foreign trade. Estimates of percentages differ, but about half of both exports and imports are German, and important amounts (e.g., of American cotton) come through Germany. The bulk of the remainder is with Poland's neighbours, notably Rumania and Austria. Great Britain takes about 7% of both imports and exports. The part played by Russia is much less than pre-War. Nor has the nature of the trade undergone much change. The exports are chiefly (a) cereals, dairy produce, timber, sugar and flax; (b) coal, iron, steel, petrol and chemicals from the mining areas; and (c) textiles. The imports are (a) fertilisers and agricultural machinery and equipment; (b) machinery and raw materials for the industrial areas; and (c) fish, cocoa, fats and other foodstuffs not produced at home.

Thus by the end of 1923 Poland was settling down to a somewhat badly organised foreign trade with a value of about £50,000,000 a year, vulnerable especially on the German side. The reform of 1924 administered a serious shock to foreign trade. Exports were rapidly surpassed in value by imports, though their total value did not diminish. But the bad harvest of 1924-5, the coal crisis and difficulties with Germany gravely aggravated the situation. Some recovery, however, appears in the autumn figures, and much was expected from the good harvest of 1925-6.

**Banking and Credit.**—At an early date the Polish banks (which had not been very strong before the War) locked up their resources in industry to a very great extent. Weakened alike by this immobilisation, by the continual decrease in the gold value of deposits resulting from inflation and by their lack of co-operation, they failed to exercise on the Government's financial policy the influence which they should have brought to bear. Such an influence was all the more necessary because of the frequent changes in the Ministry of Finance. The shaping of policy thus fell to far too great an extent into the hands of the State Loan Bank, the officials and the politicians. By 1924 the State Loan Bank had taken to itself the bulk of the business of discounting bills which would under normal conditions be transacted by commercial banks.

With the stabilisation of the currency the banks resumed something of their true importance. Some of the weaker banks disappeared. Some Government banks were amalgamated. In general, deposits increased continuously and with them discounts and advances. But interest and charges were heavy; the much-needed reforms of administration and co-operation made slow progress, and the banking system was not fully able to meet the strain of 1925. In that year it became increasingly difficult to collect inland bills, nor had the banks enough foreign resources to face the exchange difficulties without shrinking.

**Currency and Exchange.**—Much agricultural business was done by various forms of barter. Considerable quantities (for Poland) of foreign currencies were in use, especially dollar bills, which the Polish

emigrant had familiarised in the remotest villages, but no satisfactory estimates of the amount are available.

Figures of the issue of notes are as follows:—

| Date         | Circulation in millions of marks | Equivalent in thousands of dollars | Equivalent per head of population in dollars |
|--------------|----------------------------------|------------------------------------|----------------------------------------------|

These mark notes were issued by the Polska Krajowy Kasa Pospieczkowa, or P.K.K.P. (the state loan bank), a Government institution, whose dominant position in commercial banking was the special feature of Polish inflation. For its facilities it charged 7% per annum till 1923, although money generally commanded as much as 60% per annum. Its exchange regulations, though imperfectly administered, probably delayed the flight from the mark. This bank was subsequently merged in the National Bank.

**Public Finance.**—The rise in the tide of inflation overtook the Polish Treasury before it had learned to swim. Before Poland had even equipped herself with a constitution the mark had fallen to 800 to the dollar. No budget ever received the final approval of Parliament until the end of 1923, and a parliamentary system of national finance had still (1926) to be constructed.

The excessive instability of Poland's early Cabinets was a chief cause (after the war with the Bolsheviks) of her financial troubles. Another potent cause was the defective administration of the public services already mentioned. The direct financial losses from this cause were considerable.

The chief item in the expenditure was the army, which in 1921-2-3 required about one-half of the estimated or about the whole of the actual receipts from taxation, viz.: about 400,000,000 to 450,000,000 gold francs per annum (or about 12s. 6d. per head of population). This is not a large sum for a country with Poland's long, undefended land frontiers, on the morrow of invasion by Russia, and was not the true cause of the fall of the mark. A budget overbalanced by such an item is too small a budget, and in fact Polish taxation yielded far too little. The responsibility for this must be divided between the constantly changing governments, the weak administration and the citizens' century-old tradition of evading taxation.

In the autumn of 1921 M. Michalski succeeded in arresting the downward course of the mark and balancing the public accounts for a period of several months. His chief resource for this purpose was the *Danina* or extraordinary capital levy, and, skillfully employing the proceeds of this levy to maintain the exchanges steady, he was able to collect a large proportion of his taxes without their being frittered away by currency depreciation. From the *Danina* alone he collected 90% of its estimated yield.

The next event of importance in the succession of finance ministers was the Ministry of M. Grabski, who became Prime Minister and Minister of Finance in Dec. 1923.

**The Financial Reform of 1924-5.**—Grabski has claims to rank with Rasin as one of the great financial statesmen of the Continent since the War. The weakness which has lately overtaken the zloty should not obscure the great importance and high quality of his reforms, the credit for which must go in the main to Grabski himself and his immediate assistants.

Grabski's strategy may be summarised as: no foreign control, no parliamentary interference, the immediate "pegging" of the exchange, the introduction of a new currency on a gold exchange standard, and (concurrently if possible but, if not, then later) the balancing of the budget and, finally, the obtaining of certain resources abroad on the credit of the reforms thus executed. From the outset Grabski concentrated on the exchange problem, and within three weeks of receiving his full powers from Parliament he had completely arrested the decline of the mark. He achieved this result by arresting the printing press and declaring his readiness to sell exchange freely, risking the whole gold reserve of the Treasury, which amounted to only \$2,500,000. This respite allowed progress to be made with the institution of the National Bank, and especially with the national budget.

The budget problems had been a little simplified at the end of the previous administration by the "valorisation" of the taxes on Jan. 1 1924 and by the institution of monthly estimates and accounts. The immediate necessity was more cash, and Grabski, like Michalski, had to take money where he could find it. The immediate balancing of the 1924 budget was secured essentially from two sources—by the anticipation of certain taxes, and by the reimposition of a Danina. This property tax, intended to produce 1,000 million gold fr. by three equal annual instalments, served its chief purpose by producing some 200 million fr. in 1924 and over 94 million fr. in the first four months. The other leading feature of the budget reform was the turning of the railways into a practically autonomous institution.

Some gold loans were floated on the home market with moderate success. A loan of 400,000,000 lire was obtained from Italian sources on the security of the tobacco monopoly.

By these means, before the summer of 1924, the budget was rendered independent of the printing press and the major part of Poland's immediate problem was solved. But the new budget stood at the high figure of over 1,600 million zloty, and even so would have failed to balance by 160,000,000 but for extraordinary revenue such as the Italian loan. This figure is too high for Poland's resources, just as the revenue of 1922-3, estimated at about 420,000,000 zloty for each, was too low for her needs. The figure of 1,000 million suggested by Commander Hilton Young appears to be about the true figure. The expenditure of the Ministry of War increased with the increased budget, and economies in the civil administration were not carried out as vigorously as was necessary.

Meantime, the Bank Polski, the National Bank of Poland, was created by charter as a limited liability company, with a capital of 100,000,000 zloty. It has the sole right of issue of bank-notes until Dec. 31 1944. The main features of the charter resemble those adopted in Austria. Notably, the Government credit is limited to 50,000,000 zloty. When circumstances permit, the currency is to be placed on a full gold standard, but for the present is restricted to a gold exchange standard. The gold value of the currency is not fixed in the charter or by other law. The whole capital was subscribed by the public, but the Government appoints the president and approves the directors.

The first balance sheet of the bank, of May 10 1924, showed (in round millions of zloty) bank notes in circulation 111, current accounts, etc. 230; against gold 70, foreign balances 207, bills 118 and other assets 46.

This strong position resulted from the utilisation of all available reserves and the restriction of the circulation below the country's needs. But for some 12 months the bank was able to sell dollars freely at 5.185 zloty per dollar and still maintain a cover of between 50 and 70% against a minimum of 30% required by the charter.

At the end of 1924 Poland funded her chief external debts, viz., to U.S.A., Great Britain and for relief credits. The total amount of Poland's foreign debts at the end of 1925 was about £70,000,000. The first annual instalment on these debts was punctually paid at the end of 1925.

The economic consequences of stabilisation began to appear in the summer and autumn of 1924, and are still working themselves out. They were greatly accentuated by two extraneous events—the very disappointing harvest of 1924, which in itself was enough to turn the foreign trade balance against Poland, and the worldwide coal crisis. By the irony of circumstances Upper Silesia, whose detachment from Germany was much criticised in some British circles, has thus become a liability which has now to be borne by Poland instead of Germany. These two events destroyed the foreign trade surplus, which was one of the foundation stones of the reform. The other foundation stone, the balanced budget with its consequent great burden of taxation, has pressed increasingly heavily on the economic life of Poland. The gross budget for 1925 was no less than 2,176,000,000 zloty, and the net figure 1,658,000,000.

Great restriction of trade after the stabilisation was to be expected, and Austria's experience showed that it might be prolonged, but in Poland things go to greater extremes than elsewhere. The centre of the difficulties, as of the reform, has been the national bank. Its resolute maintenance of free transactions in exchange threw the burden of defending monetary stability upon its credit policy. The official rate of discount at the end of the inflation period was 48% per annum, and in practice 60% was usually payable. The Bank Polski fixed its discount rate at 12%, which was reduced to 10% in Nov. 1924, and required banks not to charge more than double the official bank rate,

but the demand for credits grew without ceasing. Those given by the Union of Banks rose from 83,000,000 zloty in April 1924 to 376,000,000 at the end of March 1925, and during the same time credits granted direct to industry by the Bank Polski increased by 221,000,000. Credit was nevertheless extremely scarce, and the repayment of loans increasingly difficult to secure. The real rates paid in private trade often considerably exceeded 2% a month. When the stimulus of inflation was removed the traditional habits of the Polish people showed themselves in these long credits. The resulting slow pace of circulation of money makes a correspondingly larger note-issue essential. In 1925 the Bank Polski rigorously curtailed credit and reduced its note issue from 551 to 369,000,000; but during the same period the Treasury issue of notes and small coins (purely fiduciary) rose to over 400,000,000, or more than the total note issue of the Bank Polski, at the end of 1925.

Prices had increased by practically 20% between June and Dec. 1924, and production fell off very seriously. Early in 1925 more stability was achieved, but the evil results of the bad harvest then began to appear. Poland was compelled to import foodstuffs for some £13,000,000, and the exchanges began to be in danger. The expiry on June 15 1925 of a coal agreement with Germany, under which Poland had been able to export some 500,000 tons a month, brought relations with Germany to a crisis, and tore the zloty away from its gold anchorage. Through the autumn the exchanges sagged lower, some of the greatest banks came into serious difficulties, and certain of them had to be granted a moratorium by the Government. Discontent increased and Grabski resigned early in Nov. 1925. A new Cabinet under Count Skrzynski was formed, with M. Zdzichowski as Finance Minister, which endeavoured to effect considerable economies in the budget and to secure loans abroad.

The initial successes of Grabski's reform have not properly been consolidated. Their permanence required them to be followed by the application of principles adopted in other European countries whose finances have been overhauled. Even more than those countries Poland requires a moderate increase of her working capital. Her pre-War history, the War and post-War inflation have prevented her from accumulating this fund from her own resources. But it would have been easier to attract it from abroad if improvements in her banking and public administration had been carried out more vigorously. A further effort at financial consolidation, if necessary with foreign help, is required if Poland is to achieve that economic strength which is indispensable to her prosperity as an independent State.

**BIBLIOGRAPHY.**—Little material is available. On economic conditions, see Reports of British and other commercial attachés; files of *Economist*; *L'Europe nouvelle*. On finance see E. Hilton Young, *Report on Financial Conditions in Poland* (1924); G. Zdzichowski, *The Finances of Poland in 1924 and 1925* (1925); *Bulletin of Polish Ministry of Finance, and Publications of the League of Nations, financial section*. The whole ground is covered in *The Polish Handbook*, ed. F. B. Czarnowski (1925). The best statistical information is in the publications of the League of Nations. (F. H. NI.)

**POLAR EXPLORATION** (see 24.938).—During the period under review (1910-26) much exploration work has been done around both the North and the South Poles. In this article a section is devoted to each of these fields. (See also ANTARCTICA; ARCTIC REGIONS.)

## I. THE NORTH POLE

As to the distribution of land and water in the northern regions, we now know the limits towards the north of all continental land surface both in the old and in the new world. The last problem in this respect was the northern extension of Greenland, the northernmost end of which was reached by Peary, while its northern coasts have been mapped by the Danish travellers: Mylius Ericksen, Knud Rasmussen, Lauge Koch and others. There seems now to be no possibility left of any great, continuous land-surface within the still unknown tracts in the North; but this does not mean that there may not be greater or smaller islands, which may possibly form a kind of continuation of the groups of islands known.

*Canadian Arctic Archipelago.*—The northern extension of the Canadian Arctic Archipelago is still an open question. Capt. Otto Sverdrup in 1900, found the great new islands, Axel Heiberg Island, the Island of Ellef and Amund Ringnes and King Christian Island, an area of more than 200,000 square kilometres. In 1916 Vilhjalmur Stefansson completed these discoveries with some smaller islands: Brock Island, Borden Island and Meighen Island, on the western and northwestern side of Sverdrup's islands. It seems hardly probable that the islands now known should form the northern boundary of this extensive archipelago; but how far it may still extend northwest and northwards will be for future exploration to decide.

*Croker Land.*—Farther east, north of Grant Land (Grinnell Land) Mac Millan has looked in vain for the land, Croker Land, which Peary thought he had seen in the distance. It may therefore be probable that there is no more land in that direction as also north of Greenland, where Peary has travelled across the drifting ice, and where there obviously is a deep sea.

*Spitsbergen.*—The extension of the island group of Spitsbergen (or Svalbard as this group is now called) is known, and as there is a deep sea to the north there is no probability of any new land of importance in that direction.

*Franz Josef Land.*—The extension of the island group called Franz Josef Land, has been explored by the Jackson-Harmsworth expedition (1895-7), the sledge journey of Johansen and Fridtjof Nansen (1895), the expedition of the Duke of the Abruzzi (1900) and by the Ziegler expedition (1902). The extension of this island group towards the east is uncertain; but the drift of the tragic Brusilov expedition in the "St. Anna" in 1912-3 east of these islands, and northwards, approximately along the meridian of 70° E., in fairly deep sea (more than 600 metres), without seeing land, limited the possibilities of this extension.

*Russian Exploration.*—By far the most important discovery in this part of the Arctic for a long time was made by the Russian expedition on board the ice breakers the "Taimir" and the "Vaigach," commanded by Vilkitski, on Sept. 3 1913, when they found the great new land or island group, called "Nicholas II. Land," to the north-northwest of the northernmost point of the old world, Cape Chelyuskin. The eastern coast of this land was found to extend towards north-northwest as a continuation of the eastern coasts of the Taimir Peninsula and the Chelyuskin Peninsula, and was tracked northwards as far as 81° N. Lat. where the ships were stopped by impenetrable ice. Only the eastern and southern coasts of this island group were observed. The group forms obviously a northern continuation of the groups of islands, Fearnley Islands and Axel Heiberg Islands, discovered during the "Fram" expedition in 1893. This new land has an extension from south to north of 350 km., or more than three degrees of latitude. How far it extends farther towards north and towards west is unknown. A limit for the possible maximum of its extension is set in the north by the drift of the "Fram" in 84° and 85° N. Lat., or about 400 km. north of the northernmost point of the known land—and in the west by the drift of the "St. Anna" at a distance of about 500 kilometres. An exploration of this island group in its full extension will be a feat of great value.

*Siberian Islands.*—Farther east are the New Siberian Islands. To the northeast of this great island group some small islands have been found in a very shallow sea: Jeannette Island, Henriette Island and Bennett Island were discovered by the "Jeannette" expedition under de Long in 1881. The last mentioned island was at the time supposed to have a great northward extension, but Eduard von Toll found in 1902, at the cost of his valuable life, that it is only a small islet of less than 200 square kilometres. In 1913 and 1914 the Russian expedition on board the "Taimir" and the "Vaigach" discovered two new small islands: General Vilkitski Island and Jokhov Island, southeast of Bennett Island. As the sea is very shallow in this region, mostly less than 50 metres deep, there may easily be more unknown islands in the north.

Farther east Wrangel Island and the tiny Herald Island are the only known islands in the shallow sea north of the Siberian

coast, not counting the islands near the land. There may possibly be more islands to the west of Wrangel Island and also in the north, north of the drift-routes of the "Jeannette" (1879-81) and the "Maud" (1922-4).

North of Alaska a deep sea has been found, and it is hardly probable that there is any new land in that region.

*The extension of the Continental Land-masses and the Deep Sea.*—To discover and map the possible islands and lands in the unknown North will be an important task for future explorers, but it will be much more important, from a scientific point of view, to define the northward extension of the continental land-masses over and under the sea-surface, and to determine in its chief features the extension of the North Polar deep sea.

*The Continental Shelf.*—The boundaries of the great continental land-masses are not defined by the coasts of the land visible above the sea, but by the edge of the *continental shelf*, which, at a comparatively small depth, generally less than 100 to 200 metres, under the sea-surface extends often very far out from the coasts, and is actually an important part of the continent. At the edge of this shelf, generally at a depth of 100 to 200 metres, the sea-bottom falls, as a rule, abruptly and comparatively steeply towards the deep floor of the ocean at depths of several thousand metres or more.

North of Siberia this continental shelf has a very wide extension of many hundred kilometres. Its surface is extremely level, and situated at a shallow depth of a large area less than 50 metres under the sea-surface. It was over this remarkably shallow continental shelf that both the "Jeannette" (1879-81) and the "Maud" (1922-4) drifted along their crooked drift-routes. The edge of this shelf has been determined only at one place, viz.: along the drift-route of the "Fram" in 1893, north of the New Siberian Islands, in about 79° N. Lat. and more than 600 kilometres north of the Siberian coast. At another place, about midway between the New Siberian Islands and Cape Chelyuskin, in about 77° 24' N. Lat., the Russian expedition on board the "Taimir" and the "Vaigach" in 1913, made a sounding of 402 metres without reaching the bottom, and here they were probably at the edge of the continental shelf. Off Nicholas II. Land the shelf seems to be comparatively narrow, and its surface is uneven and traversed by submarine valleys and fjords. But further west, towards the Kara Sea and Novaya Zemlya, the shelf is again very broad and has very shallow depths.

North of Europe this continental shelf extends far north beyond Franz Josef Land and Spitsbergen, and these island groups are situated on it. In the Barents Sea the shelf is traversed by a system of submarine valleys with depths of as much as 400 metres or more. North of Canada the continental shelf has a wide extension, comprising the whole Arctic Archipelago, but how far it extends farther north is unknown. North of Alaska, off the coast eastwards from Point Barrow, the edge of the continental shelf approaches near to the land. During the drift with the ice of Stefansson's ship the "Karluk" in 1913, and during the ice-journey of the Norwegian "Storkerson" in 1918, depths of more than 1,000 and 2,000 metres were found at distances less than 100 kilometres from land, and there seems to be an extensive deep sea.

*Sea-basins.*—During the Norwegian "Fram" expedition in 1893-6 a great and deep sea-basin with depths of 3,000 to 3,850 metres was found in the North Polar region. It extends as a continuation of the deep Norwegian Sea far north of Spitsbergen and Franz Josef Land and eastwards to the longitude of the New Siberian Islands, and probably farther eastwards.

This sea-basin forms the northern termination of a series of sea-basins which extend northward from the eastern side of the North Atlantic, through the Norwegian Sea—between Norway-Spitsbergen on the one side and Iceland-Greenland on the other. This series of deep basins separates the two great continental land masses of the earth: Eurasia on the one side, and Greenland, North America on the other. The different basins of this continuous sea are separated from each other by submarine

ridges such as: the Scotland-Faeroes-Iceland-Greenland Ridge, the low ridge between Jan Mayen and Bear Island and a probable ridge between northwestern Spitsbergen and northeastern Greenland.

How far the deep North Polar sea-basin extends eastwards towards Bering Straits and Alaska is still unknown. Nansen assumed that it actually extends to a short distance from the north coast of Alaska. The soundings made by the "Karluk" and "Storkerson," with depths of more than 3,000 metres confirm this assumption. But the extension of the deep sea in this region beyond  $74^{\circ}$  N. Lat., or 400 kilometres north of the Alaskan coast, is unknown, and we cannot decide at present whether it is continuous with the deep sea north of the New Siberian Islands or whether it may be separated from it by some submarine ridge. A single sample of the water from depths greater than 1,000 metres north of Alaska would have settled this question.

That there is an open communication in the upper water-layers between the sea north of Alaska and the sea between Spitsbergen and Greenland is proved by the drift of several objects, and there is obviously a constant, though slow, drift of the ice across the sea near the North Pole from the sea north of Bering Straits and into the Norwegian Sea where the ice drifts southwards along the east coast of Greenland. But whether this North Polar Sea is chiefly a deep sea, or whether it to a great extent is shallow, is still uncertain. By computations of the tidal observations made at several places along the Arctic coast the American hydrographer, Harris, came to the conclusion that a continuous great land probably extends from the region north of Alaska and northwest of Banks Land, to the North Pole on the one side and to a certain distance north of the New Siberian Islands on the other side. Later observations, and especially the many tidal observations and current measurements made by Dr. Sverdrup during the drift of the "Maud" (1922-5) seem to prove definitely that Harris was mistaken, and there is probably no such land to the north of the "Maud's" drift-route.

*North Polar Sea.*—The most important geographical problem of the unknown North Polar regions is consequently the extension of the deep North Polar sea. When the edge of the continental shelf has been determined all the way round it is hardly probable that there should be isolated islands farther out rising from the deep oceanic floor, unless there be volcanic islands, like Jan Mayen in the Norwegian Sea. There may, however, be submarine ridges across the North Polar basin, and they may in places rise above the sea-surface and form islands.

*Meteorological Problems* (see METEOROLOGY).—In order to master some of the most difficult meteorological problems of our atmosphere, it is necessary to study the physical conditions of the polar regions. The circulation of the atmosphere is essentially due to the heating of the air by the solar radiation in the warmer regions of the earth, and to the cooling of the air by the radiation of heat in the colder, especially the polar, regions. To try to find the laws for the atmospheric circulation without knowing the physical conditions of the extensive polar regions, would therefore be somewhat similar to trying to compute the circulation of heat in the pipes of a central heating apparatus without knowing the radiators where the heat is given off. In modern meteorology it is therefore more and more acknowledged that the meteorological conditions of the Arctic regions have a predominating influence upon the weather in our latitudes, and that therefore a thorough study of the different layers of the atmosphere—both near the earth's surface and at great heights—in all parts of the North Polar regions is essential for the understanding of the complicated laws regulating the weather.

*Oceanographic Problems.*—A methodic study of the physical conditions of the North Polar sea in the different parts of the unknown region, will be of much interest for oceanography (*q.v.*). From the drifting ice the movements of the sea, the horizontal currents as well as the vertical oscillations of the water-layers, may be continually and carefully studied at all

depths, in an ideal manner which is not possible in any other part of the ocean; and many of the greatest problems of Oceanography may thus be solved. A careful study of the relation between the directions and velocities of the drift of the ice, the sea-currents and the wind in different parts of the North Polar regions will also be of much value.

*Terrestrial Magnetism* (*q.v.*).—Investigation of the phenomena of terrestrial magnetism in the still unknown polar regions and determinations of its various elements: declination, inclination, intensity, etc., is very important and has to be attempted sooner or later.

*Problems of Gravitation.*—The floating thick ice-floes of the North Polar Sea offer possibilities of making exact measurements of the earth's gravitation over a deep ocean as well as over the continental shelf, which can be found nowhere else. Pendulum-observations of this kind made by S. Scott-Hansen during the "Fram" expedition (1893-6), gave unexpected results; but with modern instruments results of very great importance for the understanding of the physics of the earth and its crust may certainly be obtained (see GEODESY).

*Biological Problems.*—There are naturally also biological problems of interest in the unknown polar regions, although they may seem to be of minor importance. The North Polar sea, covered in its interior by an almost continuous layer of thick ice, is extremely poor in plant as well as animal life. The sun light is absorbed by the thick ice, and extremely little light penetrates to the water underneath. Hardly any plant-life can therefore be developed in this water, there is only just a little—chiefly in the water lanes between the floes in the summer; and without plant life, no animal life. The interior, continuously ice-covered North Polar sea may therefore be considered as a desert in the ocean, where the "Fram" expedition (1893-6)—"found comparatively many species of small crustaceans, but the fauna was so extremely poor in number of specimens that the tow-nets might hang out for several days, and although we drifted along at a good speed there was extremely little in them when we hauled them up." These conditions have a peculiar effect. The substances in the sea-water generally used to sustain the plants and animal life of the sea, are thus used only to an extremely small extent in the ice-covered North Polar sea, and the result obviously is that these substances are to a great extent stored in the sea-water of that region. But as soon as this water with these accumulated riches is freed of the ice, near the outskirts of the polar sea, and is exposed to the sunlight in the spring and summer, an unusually rich plant and animal life (plankton) is developed and flourishes. It would certainly be of great importance for the understanding of the biology of the ocean in general to study in detail the biological conditions in the North Polar regions.

*Methods of Exploration.*—The most important problems of the unknown North Polar regions have been mentioned above. We have hitherto had chiefly three means for locomotion for the exploration of the polar regions, viz.: sailing in a ship, sledge-travelling with or without dogs (or reindeer or horses) and drift with the ice. The use of the first of these methods is limited by the impenetrable ice preventing the advance of the ship. The second method has a limited radius of action, owing to the difficulty of transporting a sufficient equipment and the accommodation necessary for the desirable scientific research. The third method of locomotion is very slow and has the drawback that the traveller cannot decide the direction in which the ice will carry him. But if the expedition drifts in a well-equipped ship, this method has the great advantage of offering the best possible opportunities of making methodic and valuable scientific investigations even of the most subtle kind.

In recent times we have, however, acquired two new means of locomotion which may become of great importance for the unknown or little known regions of the earth; the aeroplane and the airship.

Owing to the difficulty of landing on the uneven North Polar ice, the use of the aeroplane with its present development has obviously its limitations in the North Polar regions, as is proved

by Amundsen's remarkable flight to nearly 88° N. latitude. But it can hardly be doubted that when it is further developed it will become of importance for the exploration of these regions.

The airship on the other hand, may be used not only for solving the geographical problems of the unknown North Polar regions, by flying across them; but it may also render possible more continuous investigations in the unknown regions as, with the considerable carrying capacity of a big airship, parties of men with full equipment may be dropped at any place either on land or on the drifting ice in the unknown regions, and may be fetched again at any fixed time when they have fulfilled their work.

(F. N.)

*Air Expeditions to the Pole.*—No less than six air expeditions were organised to fly to the North Pole in 1926. Particulars of each are given below.

1. The Amundsen-Ellsworth-Spitsbergen-Alaska, 1926, expedition used the Italian semi-rigid dirigible airship type N. 1, named "Norge," and carried 17 passengers, including Amundsen, Ellsworth and Col. Huberto Nobile, who commanded the airship. The "Norge" cruised to Spitsbergen in March and April, by way of Rome, Marseilles, Paris, Pulham, Leningrad (or Oslo), Vardoe, Kings Bay. Starting from Spitsbergen May 11, the "Norge" flew to the Pole, which it circled twice, thence across the unexplored Arctic basin to Point Barrow, Alaska, and landed at Teller, on Behring Sea. The total distance traversed was 2,700 m. and the time occupied 71 hours.

2. The expedition organised by Lieut.-Commander Richard E. Byrd, U.S.N., to which John D. Rockefeller, Henry Ford and three others have subscribed \$20,000 each, for the scientific purpose of exploring the area from the Arctic edge of the North American continent to the Pole. Commander Byrd left Spitsbergen at 12:50 A.M. on May 9 1926 and returned there after a 15½ hours flight in the course of which he reached the North Pole.

3. The Detroit Arctic Expedition, commanded by Capt. George H. Wilkins, the Australian aviator-explorer, who will fly from Point Barrow to Spitsbergen, using two Fokker aeroplanes, which will be transported by railroad to Fairbanks, where the railroad ends, and then flown to Point Barrow. The Alaskan mail pilot, Ben Eilson, will be in charge of the planes.

4. The Norwegian expedition organised by Lieuts. Ellassen and Gross of the Norwegian Navy, who propose to fly a seaplane from Novaya Zemlya to Alaska, a distance of 3,000 kilometres, which they expect to cover in 30 hours.

5. The American expedition organised by Lieut. Leigh Wade and H. H. Ogden, U.S. Army, who distinguished themselves in the round-the-world flight, and left the army to organise this expedition. With them are associated Robert Anderson Pope, who conceived the expedition, Norman H. Read, veteran pilot, who was one of the first Americans to join the Royal Air Force, Lowell Thomas, writer and photographer, Harry Ehler, mining engineer, and L. L. Jackson, radio expert, geologist and meteorologist on the staff of the Museum of Natural History.

6. The Harrison Williams expedition in charge of Capt. Robert A. Bartlett.

(X.)

## II. THE SOUTH POLE

*Amundsen 1910-1.*—Captain Roald Amundsen set out in the "Fram" for a north polar voyage in the autumn of 1910, but changed his plans and established a base called Framheim, on the Antarctic ice barrier near the Bay of Whales in Ross Sea (78° S.). Before winter he had laid out food depots in 80°, 81° and 82° S. and after winter, on Oct. 20 1911, he set out with four companions on ski and 52 dogs dragging three sledges. They crossed the barrier southward to the Queen Maud mountains and found a way to the Plateau by the Axel Heiberg glacier in 85° South. In 88° S. the surface was 11,000 ft. above the sea and thence a gentle descent brought the party to the Pole on Dec. 14 1911. Two days were spent in fixing the exact position. The outward journey occupied 49 days, the return to Framheim only 38, the dogs working well throughout. The party at the base had meanwhile visited King Edward Land where they reached a height of 1,700 feet.

*Scott 1910-2.*—Captain Robert Scott organised a private British expedition in 1910, and landed from the "Terra Nova" at Cape Evans on Ross Island (77½° S.) on Jan. 4 1911. He built a hut for his land-party of 24 which included a highly efficient scientific staff, and sent the "Terra Nova" with a party under Commander Victor Campbell to occupy a base in King Edward Land. This party met Amundsen, returned to Cape Evans with news of the Norwegian expedition, and proceeded to Cape Adare where they wintered in the hut of Borchgrevink's expedition of 1899-1900. They were compelled to make a hazardous land journey of 300 m. back to Cape Evans along the coast of Victoria Land, wintering on the way with improvised equipment. On this journey Mr. R. E. Priestley made valuable geological surveys. In 1911 and 1912 Griffith-Taylor and Debenham surveyed the west coast of MacMurdo Sound. A very remarkable winter journey to Cape Crozier was carried out by Dr. E. A. Wilson, Lieutenant Bowers and Mr. Cherry-Garrard in conditions of unprecedented severity, and unique specimens of the eggs of the emperor penguin were secured.

The main effort of the expedition was a journey to the Pole. Depots were laid out on the barrier, but only as far as 79° 29' S., in Jan. and Feb. 1911. The expedition started from Cape Evans on Oct. 24 1911 in three divisions using respectively motor-sledges, ponies and dogs. The motors broke down before the journey was well begun, the last of the ponies was shot before reaching 83° 30' S., here also the dog-teams were sent back to the base, and on Dec. 10 Scott with 11 others began the ascent of the Beardmore glacier, following Shackleton's route of 1909, with three man-hauled sledges. On Dec. 21 four men with one sledge were sent back from 85° 7' S., and on the 31st the last supporting party of three under Lieut. E. R. G. R. Evans returned from 86° 56' S. and reached the base after narrowly escaping death from scurvy.

The Polar party—Scott, Wilson, Bowers, Captain Oates and Petty-Officer Edgar Evans—with one sledge and equipment originally designed for four men, reached the Pole on Jan. 18 1912 where they found a tent left by Amundsen. All were tired out by their 69 days' march and bitterly disappointed to find that they had been forestalled. The weather on the return journey was worse than had ever been known before, and disasters followed one another. Edgar Evans broke down on the Beardmore glacier and after delaying the march died on Feb. 17. Oates, at the end of his strength, and resolved not to be a burden, sacrificed himself on March 17 in 79° 50' S., by walking out into the blizzard. The supply of fuel oil at the last depot had been deficient and 20 m. remained, to reach the next. The three survivors struggled on heroically for 10 m., raised their tent for the last time and, being without fuel, nothing remained but to await death with quiet fortitude. Lieutenant Evans, the second in command, had been invalided home on the "Terra Nova," and the search parties sent out to meet Scott had been unfortunate, so that it was not until after another winter that Dr. Atkinson, then in command at the base, found the tent with the frozen bodies on Nov. 12 1912.

*Douglas Mawson.*—Dr. Douglas Mawson organised the Australian Antarctic Expedition which set out in the "Aurora" in Dec. 1911. A party was landed on Macquarie Island to set up an intermediate wireless station and the ship went on to Adelie Land where the main base was established and a wireless mast erected. Here Mawson with 17 companions built a hut on the shore of Commonwealth Bay (67° S., 142° 4' E.) while the ship under the command of Capt. J. K. Davis proceeded 1,500 m. to the westward where Queen Mary Land was discovered and Mr. Frank Wild landed with a party of seven men and a hut to form the Western base in 66° S., 94° East. Adelie Land was found to be a region of almost continuous blizzard, the wind-force averaging 50 m.p.h. for the whole year, and velocities of over 100 m.p.h. frequently occurring. Sledge parties started from the main base in Nov. 1912, diverging to explore inland towards the magnetic pole and eastward and westward near the coast. The land sloped steeply from the sea to the high plateau and was entirely buried in heavily-crevassed glacier ice

and snow, yet the sledge parties made their way for 300 m. or more from the base. All got back without disaster except the leader, whose two companions, B. B. S. Ninnis and X. Mertz, perished, leaving him with scant stores 100 m. from Commonwealth bay. He reached the hut on Feb. 10 1913 by an effort of almost superhuman endurance and found that the "Aurora" had just sailed to relieve Wild, leaving a volunteer rescue party with whom he awaited the return of the ship in Dec. 1913.

*Filchner 1911-2.*—Lieut. W. Filchner got up an expedition in Germany and sailed from South Georgia in the "Deutschland" in Dec. 1911. He made his way into the Weddell Sea on the meridian of 30° W. and found a new coast, which he named Luitpold Land in 77° 48' S. on Feb. 2 1912. An attempt to erect a winter hut in Vahsel Bay was frustrated by ice movements, and after seeking vainly for safe winter quarters Filchner decided to return to South Georgia on March 4. The ship was caught in the floe and drifted slowly northward and eastward for 264 days until the floe broke up and set her free in 63° 40' S., on Nov. 27 1912. Good meteorological work was done, especially by kites in the upper air, and the drift threw light on the currents of the Weddell Sea, and proved the non-existence of Morrell Land.

*Shackleton 1914-6.*—Sir Ernest Shackleton planned the Imperial Trans-Antarctic Expedition in 1914, intending to cross the Antarctic continent from the Weddell Sea to the Ross Sea by way of the South Pole. On board the "Endurance" he entered the ice-pack in the Weddell Sea early in Dec. 1914 and worked his way in adverse climatic conditions southward between 15° and 20° West. He discovered the Caird coast between Coats Land and Luitpold Land on Jan. 11 1915, but he found no landing place, so the fine teams of Hudson Bay dogs and several new types of motor sledges and tractors were useless. The ship, beset in the ice on Jan. 18, was drifted northward parallel to the track of the "Deutschland" but about 10° farther west. She was crushed in a terrific ice pressure and abandoned on Oct. 27, in 69° 5' S., and the 28 men camped on the ice-floe, which continued to move northward until April 9 1916 when the floe broke up in 62° S., 54° W. after a drift of 457 days. The party took to their three small boats and landed six days later after extraordinary hardships on Elephant Island where they camped on a narrow beach below vertical ice cliffs. Shackleton with five men succeeded in reaching South Georgia, 750 m. distant, in a 22-ft. boat and after three unsuccessful attempts to return to Elephant Island through the ice-floes he succeeded with the Chilean trawler "Yelcho" in rescuing all his men on Aug. 30 1916.

*Shackleton's Ross Sea Party, 1914-7.*—The Ross Sea party who were to meet Shackleton after crossing the continent reached Cape Evans in the "Aurora" on Jan. 16 1915 and Captain Mackintosh with five men carried out his task of laying a depot at the foot of the Beardmore Glacier in Jan. 1916. Meanwhile the "Aurora" trying to winter frozen in the ice at Cape Evans was blown out to sea fast in a floe in May 1915 and drifted northward for 315 days. Though much damaged when the ice broke up near the Balleny Islands she got to New Zealand, was repaired and in Jan. 1917 returned to Cape Evans under the command of J. K. Davis with Shackleton on board. The vessel rescued the survivors of the Ross Sea party; three of them had already perished, one on the march, from scurvy and two by taking undue risks on the sea-ice.

*Shackleton's Last Voyage, 1921-2.*—Sir Ernest Shackleton's last expedition sailed on the "Quest," a small and defective vessel, in Sept. 1921 to explore the Enderby quadrant of the Antarctic (0° to 90° East). The leader died at South Georgia on Jan. 4 1922, but Frank Wild, second in command, carried on the voyage as far as the lateness of the season permitted. He reached 60° 17' S. in 17° E., in spite of great difficulties, and got important soundings in a little-known area.

Whaling on a large scale is now carried on in Antarctic waters from South Georgia and Australia, but no geographical discoveries have resulted. The Royal Research ship "Discovery" was commissioned in 1925 by the Colonial Office with funds

supplied by the Falkland Islands Govt. to study the life history of whales with the view of regulating and perpetuating the industry in sub-Antarctic waters (see WHALING).

*Scientific Results.*—Results of exploration since 1910 have been the attainment of the South Pole, the discovery of the general configuration of the Antarctic continent and the perfecting of methods of polar travel and residence. The geology, glaciology and biology of large areas have been studied in some detail. The most valuable work has been done in meteorology, the combined observations of all the expeditions having thrown much light not only on Antarctic weather, but on the general circulation of the atmosphere which affects all countries. The full results of the Australian expedition and of Shackleton's two last expeditions had not been published up to 1926. It has been established that the blizzards of Adelie Land and MacMurdo Sound are outrushes of air chilled by the intense cold of the great plateau and pouring down the slopes by gravity. The even greater cold found at sea-level at the Bay of Whales is accompanied by a remarkably still atmosphere.

Part of the funds raised for a memorial to Scott has gone to endow the Scott Memorial Institute for Polar Research in the University of Cambridge where polar problems may be studied, and exploration promoted.

**POLISH LITERATURE** (see 21.923).—During the last decade of the last century there came to the fore a whole group of young exuberant talents. Dissatisfied with the utilitarian character of art and poetry of the preceding period, they organised themselves into an independent body with the view of working out a new theory of art. This group, soon known as "The Young Poland," rejected all accepted and conventional views of art and literature as a national function, and demanded an absolute freedom in form and matter. True to their principles of unfettered individuality, practically everyone tried his best to find his own way of expression.

*A Group of Poets.*—The first among these young poets to gain fame and renown was Kazimierz Tetmajer (b. 1865), whose love lyrics are comparable to the best work of French Parnassists. The modern poetry of France and Belgium found a gifted and congenial interpreter in the person of Zenon Przesmycki (b. 1861). The most forceful individuality of this group was Stanisław Przybyszewski (b. 1868) who, having spent several years among the young Scandinavian and German writers, came back to Poland in 1898 and became at once the leader of the group and the editor of their organ, a weekly called *Życie* (Life). His dramas, full of fatalistic terror, and his prose poems, dealing with the mystical and tragic side of love and death, became the fashion of the day.

The art editor of the said weekly was Stanisław Wyspiański (1869-1907), a painter of great originality, who became also the leading Polish dramatist; in fact, an artist and a man of the theatre who contributed not a little to the development of the art of the theatre. His leading idea was to unite in the theatre the arts of painting, of architecture and of drama, in which poetry and music should have their due share. The study of the Greek tragedy inspired him to works like *Meleager* and *Protesilas i Laodamia*. His next experiment was to apply the form of Greek tragedy to the setting of a Polish village in the two

tragedies *Klatwa* (The Curse) and *Sędziowie* (The Judges). But gradually his attention turned to national subjects, and especially to the problem of national strength and weakness, which is the root of the three dramas based upon the history of the Rebellion of 1831, *Warszawianka* (The Song of Warsaw), *Lelelew* and *Noc Listopadowa* (The November Night). *The Legion* (1900)—a play of which the tragedy of Mickiewicz as the leader of Polish romanticism is the subject-matter—constitutes the link between the past and the present day. The present day problem was to Wyspiański that of national existence, which he dealt with in three powerful dramas—*Wesele* (The Wedding) (1901), *Wyzwolenie* (The Deliverance) and *Akropolis* (1904).

Jan Kasprówicz (1860) is no doubt the greatest contemporary Polish poet. With him, not unlike Thomas Hardy, the problem of evil and human suffering is the predominant subject. From the first small volume of poetry, published as far back as 1889, this problem, inseparable from that of God and religion, finds expression growing more and more powerful in *Chrystus* (Christ) (1904), *Na Wzgórzu Śmierci* (On the Hill of Death) and finally in the cycle of hymns dedicated *Ginącemu Światu* (To the Perishing World) (1899-1901). Here the poet reaches the simplicity and the heights of Job or Aeschylus. The echoes of the Promethean struggle of man are heard in many of his works, until at length the poet attains the wisdom of a resigned sage, which speaks from every line of his last work called *Księga Ubogich* (The Book of the Poor) (1916). The mood of spiritual calm is also the dominant tone of Leopold Staff (1878) who started his poetical career with *Sny O Potęgę* (Dreams of Might). A cruel death at the hands of Russian Bolsheviks brought to an untimely end the life of Tadeusz Miciński (1873-1919), a poet endowed with extraordinary imagination, and a visionary of a deeply religious nature.

*The Work of Żeromski.*—Brought up in the atmosphere of the most stupid Russian oppression and persecution, Stefan Żeromski (1864-1925) at that time one of the leading Polish novelists of his time, introduced the painful and profound pessimism of a modern mind tormented by the endless sight of wrong done by man to his fellowman, and of the apparent triumph of evil. This pessimism underlies the conception of his many novels depicting the utter futility of individual effort and self-sacrifice. The most typical among them are *Ludzie Bezdomni* (The Homeless) (1900) and *Walka z Szatanem* (The Fight with Satan), a trilogy published at intervals during the War.

One of his outstanding artistic achievements is a great historical novel dealing with the Napoleonic period, *Pobioty* (The Ashes) (1904). The stately classic prose of Sienkiewicz is here displaced by a new literary language able to reproduce a new mood and full of rhythm. But the difference between Sienkiewicz and Żeromski goes a step further. While the former was anxious to rouse the national feeling by his artistic calling to life of past glories, Żeromski, as if by contrast, does not shrink from the analysis of the most painful social and national ills. His last novel *Przedwiosnie* (Before the Springtime) comes as a timely warning against the dangers threatening the social fabric of Poland. The ideal of independent Poland was with him as sacred as with Wyspiański.

*Reymont.*—In popularity second to none, and in his standing surpassed only by Żeromski, is the fortunate winner of the Nobel Prize for literature (1924), Władysław Stanisław Reymont (1868-1925), whose artistic point of view, however, altogether differs from that of Żeromski. He is mainly concerned with life as it is. His joy and delight is to be one of the mass, a particle in the eternal movement. His acute sense of observation and his strong, almost brutal directness in execution manifested itself in his short stories which deal with the life of peasantry. But his early ambition was to make a picture of life in a big industrial town. With this end in view he went to Łódź, the main centre of Polish textile industry, and having spent there a few months, he produced his famous novel called *Ziemia Obiecana* (The Promised Land) which brought him, on the part of the critics, the title of "Polish Zola." It was the apparently simple and monotonous, yet rich, complex, and varied life on the land, the life of the peasant,

that became his main subject. Having once set his mind and heart on this theme, Reymont devoted to it five years of hard and incessant work until his great tetralogy called *Chłopa* (1904-9) was finished, Eng. tr., *The Peasants* (1925). This is a great epic novel, an achievement unique of its kind in the annals of modern literature. Although the psychology of the people remains faithfully Polish, the work attains a universal importance by its fullness and completeness of treatment.

Reymont's *The Peasants* was to a certain degree the crowning achievement of the movement which aimed at an artistic introduction of the popular element into art and literature. As far as literature was concerned, this aim was partially and locally realised in some of the plays of Wyspiański, and even more effectively in a series of short stories of Tetmajer published under the title of *Na Skalnem Podhalu* (On the Polish Rockies), in which the author succeeded in re-creating the vanishing primitive life of the natives of the Polish Highlands. These stories led him finally to a long novel called *Legenda Tatr* (The Tatra Saga). The interest in the life and manners of Polish Highlanders soon became fashionable, and a whole group of poets and prose writers followed his example. Among them the strongest individuality is that of Władysław Orkan who, like Tetmajer, was born and brought up in these parts of Poland.

*Other Writers.*—The most talented representative of exoticism in Polish literature is Wacław Sieroszewski (1858), whose works deal mostly with life in Northern Siberia and the Far East, which he got to know when banished thither by the Russian authorities for a political offence. His prolonged stay among the native tribes of Northern and Eastern Siberia resulted in a series of most fascinating and interesting short stories, in which the hard lot of primitive life of these Siberian tribes is presented objectively, yet not without humanity and understanding. His novels on life in Japan and China possess the same humanitarian qualities.

An artist of rare subtlety and perfect artistic skill is Wacław Berent (1873). Among his few novels the most important are: *Próchno* (Rot) and *Ozimina* (Winter-Sowing), containing a most subtle analysis of life at the end of the 19th century; his later work, *Żywe Kamienie* (Living Stones) (1918), an amazingly rich and interesting picture of mediaeval life, revealed a new and unexpected aspect of his talent. Among the novelists who chose to follow the path made safe by the genius of Sienkiewicz's contemporary novels the most talented is Józef Weyssenhof (1860), while of the novelists who belong to the school of Żeromski the most conspicuous are Gustaw Daniłowski, Andrzej Strug and Madame Rygier-Natkowska. The element of satirical humour is represented in the works of Kornel Makuszyński, Jan Lemanski, Adolf Nowaczynski and Włodzimierz Perzyski.

*The Influence of the World War.*—These are the most important writers of the older generation. With the normal conditions of spiritual and intellectual development restored, Polish literature must resign a good deal of its former position as one of the guiding forces in national life. At the close of this period a great new movement, although necessarily of a somewhat chaotic and transitional character was making itself felt. The most distinct and definite advance is to be found in poetry. We may trace its origin to the War. Already during the World War which for the Polish youth was the war of emancipation and freedom, there came into being two notable groups of young poets, one in Poznań, the capital city of the Western provinces of Poland, another in Warsaw. The latter soon surpassed the former and from 1920 onward became the centre of the new poetic movement which was at first characterised by a boldly aggressive and joyous view of life. Among these young poets the most promising are Julian Tuwim, Kazimierz Wierzyński, Jan Lechoń, Antoni Słonimski and Jarosław Iwaszkiewicz. There are others who, like Emil Zegadłowicz, look for their inspiration to the quietness and retirement of a country life, seeking rather solitude and loneliness than the distracting crowd.

War experiences found expression in some notable works of such writers as Madame Kossak-Szczuka, Eugeniusz Konoin-Malaszewski; Madame Dunin-Kozicka and above all Juliusz

Kaden-Bandrowski. The scattering of the Polish exiles over the vast territories of European and Asiatic Russia called into being at least one writer of unsurpassed energy and imagination in the person of Ferdinand Goetel. An enormous popularity in Poland, as well as abroad, was won by a writer of amazing experiences, Ferdinand Ossendowski; his books were quite a revelation to the minds of American and Western European readers.

The immediate post-War Polish problems, reflecting the social and political changes brought about by the collapse of the pre-War systems prevailing in Germany and Russia attracted soon a great deal of attention on the part of several writers of the older generation, notably of Zygmunt Bartkiewicz and Adam Grzymała-Siedlecki. The historical novel which played such an important part in the literature of the last century appeared to be on the decline; the call of the present with its new problems was too urgent to leave much time for brooding over the past.

See Roman Dybowski, *Periods of Polish Literary History* (1923) and *Modern Polish Literature* (1924). (L. P.)

#### POLITICAL ECONOMY: see ECONOMICS.

**POLIVKA, JIRI** (1858— ), Czech philologist, studied at the universities of Prague and Zagreb. In 1885 he became a lecturer, and in 1895 was appointed professor of Slavonic philology in the Charles University at Prague. He travelled on several occasions in Russia and in Yugoslav countries for the purposes of research. His writings, which are contained mainly in Czech and foreign philological and Slavistic periodicals, deal with many questions relating to grammar, literary history and folklore. His chief works are "Palaeographische, grammatische und kritische Eigentümlichkeiten in dem Makedonischen Praxapostolus," *Archiv, für Slav. Phil.* X., pp. 106-132 and 417-483 (1887); "Novější hypotese o původu písem Slovanských," *Listy filologické* XII., pp. 92-120 (1885) and *Drobné příspěvky literárně-historické* (Prague, 1891). Prof. Polivka made a special study of popular literature and analysed several collections of popular legends, especially those of the Slavonic races. His chief work of this character is "O Srovnávacím studiu tradic lidových," *Národopisný Sborník Českoslov II.* pp. 1-49 (1898). For a list of his works see J. Horák, *Sborník Prací věnovaných Prof. Dr. J. Polivkovi* (Prague, 1918).

**POLO** (see 22.11).—The years 1910 and 1911 witnessed a great transformation in English polo. In 1910 the handicapping of individual players was introduced and in 1911 offside was abolished. These changes were to a large extent in consequence of the sensational defeat of England by America in 1909.

As regards offside it was realised that the drawback of curtailing the liberty of one of the four players in a team by making him adapt his movements to those of his chief opponent, i.e., the back on the opposite side, was an unfair one. The position of No. 1 under offside conditions was very unpopular; the youngest and most inexperienced player was, as a rule, chosen for this unenviable position, being often used simply to clear the way for his No. 2 by riding off the back, and being ordered to leave the ball alone, with the result that he very frequently spoilt his ponies and failed to improve his own play. Offside slowed up the game, and it was realised that the wonderful form shown by the great American team (No. 1 L. Waterbury, No. 2 M. Waterbury, No. 3 H. Whitney, back D. Milburn) had been developed by playing the game at a greater pace under no offside conditions. Lastly, with the offside rule in force, umpiring was extraordinarily difficult.

**Handicapping.**—The individual handicapping of players must not only tend toward closer and harder matches, and consequently more interesting games, but must also give the stronger side more practice in goal hitting than under offside conditions; and in all tournaments, with the exception of open cups, the stronger teams would be obliged to give a start to weaker combinations instead of playing on the level, as was the case under the "recent form list" which had been in force since 1903. The "recent form list" was a list of first-class players and in ordinary tournaments only one or two such players might play in the same team. On the whole, the abolition of

offside and the introduction of the system of handicapping improved the game all over the British Empire, for India and the Dominions followed Hurlingham's lead. Matches were closer and combination was not lost.

**Polo Ponies.**—Up to 1914 the height of ponies was limited to 14.3, official measurers being appointed in England and Ireland. The height measurements were unsatisfactory for many reasons. Cruelty was practised, big ponies with low withers were passed, smaller ones with high withers failed to get through and much expense was entailed. Further, big ponies that failed to pass were promptly sold in the United States, where no measurement rules were in force and in some instances were played in international matches against England.

When the War was over measurement of polo ponies was entirely abandoned. Owing to the losses of thousands of ponies in the War, the cessation of breeding and the consequent difficulty of finding sufficient 14.3 ponies, it was decided that animals of any height might be played. A craze at first rose for big ponies, but it was soon found that the game deteriorated owing to various causes, the chief of which was that what the big ponies gained in pace they lost in handiness. Owing to the scarcity of English ponies, England has become more and more dependent on the Argentine supply, the pony from that country having marvellously improved in quality.

**International Polo.**—Till 1909 it was not really believed that there was any team in the world that could possibly beat the best English players and the great interest taken now in international polo may be said to have then started. International polo matches have turned polo from what it used to be, more or less a private club game, into a great popular spectacle. The zenith of English polo was reached in 1914 when the Championship Cup, lost in 1909, was brought back to England by Lord Wimborne's soldier team (Captain Leslie Chase, H. A. Tomkinson, F. W. Barrett and V. N. Lockett). In 1911 and 1913 attempts were made to recover the cup, which was only lost by the narrowest of margins and in 1914 victory crowned the efforts of the English team. Then came the War in which many of the best English players lost their lives and during which the training of the young players in polo, and of the boys in riding, ceased for about five years. When it was resumed, the expenses of the game had increased to such an extent that few young civilians could afford to take up the game at all. In England the standard of play had deteriorated, and English teams suffered heavy defeats by America in 1921 at Hurlingham and in 1924 in America. In 1922 an excellent Argentine team visited England, and in 1925 the Jodhpur team came from India. Both of these teams succeeded in winning the Championship Cup, the former going on to America to annex the U.S.A. championship. In 1923 the British Army team was defeated by the American Army in the United States, and in 1925 was again defeated by the American Army in England.

During 1926 perhaps the most hopeful sign for the future of the game in England was the great interest taken by the general public and the tremendous keenness of the players themselves. This is undoubtedly due to the international matches, the visits to England of Argentine, Jodhpur and U.S.A. Army teams and to the fact that the public has been able to witness good matches at Hurlingham, Rugby, Minehead, Cirencester and elsewhere.

**United States.**—Polo as played in the United States is a highly scientific, hard-working, out-to-win game. English polo in comparison is slow because so much play is concentrated on the principal fields, in consequence of this the turf and top dressing are badly cut and therefore slow; whereas in the United States there are many exceedingly fast fields on which important matches are played. On these fast fields the slow-field player is confused. Within half an hour's motor ride of the Meadow Brook Club, near New York City, are ten or twelve fast fields, two of

which are conserved to keep them in perfect condition; in the corresponding fields around London two and sometimes three matches are played at each day's gathering. Then, in England, of recent years high-goal men play much with lower-goal men, while in the United States high-goal men play with their handicap peers to a much greater extent, thus continually holding themselves to their highest point of excellence. There is a difference also in method employed in the game. The seat in the saddle is deemed in America as important as the stance at golf; American players hit standing in the stirrups, hit from the heel to the shoulder, whereas Englishmen mainly hit from a seat in the saddle. In the United States novices and even schoolboys are encouraged to take up the game; in a number of places polo is played through the winter by these youngsters under the enthusiastic supervision of crack players from important clubs, who willingly give time and experience to train properly the next generation in this great outdoor game. (W. P. P.)\*

**POLYTECHNICS:** see TECHNICAL EDUCATION.

**POMARE, SIR MAUI**, Maori statesman, was born at Pahou, Taranaki, New Zealand, his father being chief of the Atiawa tribe and his mother a chieftainess of the Ngalitoa tribe. He was educated at a private school at Christchurch and the Te Aute College, Hawkes Bay, and studied medicine at a medical college in Chicago, gaining a doctor's degree. He was appointed chief health officer to the Maoris, was knighted in 1922 and in the following year became Minister for Health. He was also appointed minister for the Cook and other islands and minister representing the Maori race.

**PONTOPPIDAN, HENRIK** (1857– ), Danish author (see 22.69), completed *Lykke Per* in 1904. In 1912–6 appeared his trilogy *De Dodes Rige*, dealing with the first decade of the 20th century. In 1917 he received the Nobel Prize for literature, together with K. Gjellerup.

**POOR LAW** (see 22.74a).—Ever since the exposures made by the royal commission on the Poor Laws in 1909, the whole British system of boards of guardians and parish relief has been, so to speak, under sentence of death. Mr. John Burns, President of the Local Government Board at that date, tried to save it by administrative reforms. But those reforms left the fundamental defects of the Poor Law untouched, and they did little to restore it to popular favour. The World War brought a temporary reprieve; the volume of pauperism diminished, and in any case drastic reform would have been impossible under war conditions. (See also INSURANCE, SOCIAL.)

*Recommendations of 1917.*—In 1917, however, a committee, appointed by the Ministry of Reconstruction and presided over by Sir Donald Maclean, re-examined the problem. Its report confirmed the sentence passed by the royal commission eight years before, and made detailed recommendations for the break-up of the Poor Law. It proposed:—

1. The transfer of all the functions of the boards of guardians to the councils of counties, county boroughs and boroughs or urban districts with populations exceeding 50,000.

2. Provision for all the sick and infirm (including the aged requiring institutional care, and maternity cases and infants) should be made by these authorities under the Public Health Acts suitably extended.

3. The Ministry of Health should have power to put any borough with a population over 10,000, or any urban district with over 20,000, in the position of an autonomous health authority, with such reservations as might be desirable.

4. The children should be dealt with by the local education authorities, the mentally deficient by the local lunacy authorities.

5. Every county or county borough (or borough or urban district council with a population over 50,000) should set up: (1) a prevention of unemployment and training committee (on the lines of the education committee, and including representatives of employers and trade unions); (2) a home assistance committee (on the lines of the education committee) to enquire into the economic circumstances of all applicants for public assistance, to supervise them, to administer all relief given in the home, to recover expenses of maintenance, treatment, etc., and to keep a private register of all such applicants and their families and of the assistance given.

6. County councils should appoint committees for districts or combinations of districts, to which various functions of the home assistance committee and the prevention of unemployment com-

mittee would be delegated. Such district committees would consist of: (a) members of the county council; (b) borough or district councillors; (c) persons experienced in the work to be done.

7. London should have a special scheme, in which the functions would be divided between the L.C.C. and the metropolitan borough councils. The borough councils would appoint home assistance committees, and would also be responsible for vaccination and registration of births and deaths. The L.C.C. would, through its appropriate committees, exercise the rest of the functions transferred. It would also appoint a central assistance committee, which would lay down a policy and rules of local administration for the home assistance committees in the metropolitan boroughs.

8. Poor Law officials should be transferred to the local authorities (provided both they and the local authorities agreed), and compensated for any pecuniary loss incurred by the change.

9. The cost of all functions transferred should fall on the new authority (the county, county borough, borough or urban district and in London mainly on the county, but partly on the metropolitan borough).

Scotland was outside the committee's terms of reference. But the matter was referred for consideration to the Scottish consultative council on local health administration. The council issued majority and minority reports, the majority declaring in favour of a Scottish scheme on the general lines of the Maclean report.

*The Recommendations Examined.*—These reforms were not advocated on the ground that the boards of guardians were corrupt or incompetent or remiss in their duty. Broadly speaking, the guardians were recognised to be doing devoted service. But it was the service of an out-of-date principle; relief of the poor by an *ad hoc* destitution authority, employing—and obliged by law to employ—deterrent methods, could not be squared with modern views either of scientific treatment or of efficient administration. And, indeed, it was this very fact which had caused an all-round encroachment on the guardians by other public bodies, better equipped for dealing with the needs of this or that class of the poor. As the Maclean committee put it: "For the last decade Parliament has been unwilling to entrust the boards of guardians with new functions, and the provision for new services has had to be made by other local authorities—in some cases new local authorities—often to the increase of confusion." Thus, with the reversal in 1911 of the "pauper disqualification" clause in the Old Age Pensions Act of 1908 many thousands of the destitute aged became entitled to old-age pensions, and so passed out of the Poor Law. Similarly the National Health Insurance Act took a vast number of patients, or potential patients, from the Poor Law medical service, while later Acts, empowering the local health authorities to set up maternity and infant clinics, to provide midwifery service, to supply milk to expectant and nursing mothers, to treat venereal disease or tuberculosis, still further diminished the scope of the Poor Law.

All this served to reinforce more and more strongly one of the principal charges made by the royal commission in 1909. For it meant in practically every department an increase of administrative disorder—overlapping, multiplication of machinery and waste. In the case of every class of the pauper host, infants, children of school age, the sick, the feeble-minded, the aged, the able-bodied, there was at least one, and generally more than one, other authority set up as a rival to the board of guardians. There was little, if any, co-ordination between the work of the medley of public bodies engaged in giving various forms of assistance out of the rates and taxes. They were in many cases dealing on different lines, and for different reasons, with different members of the same family. So far as the Poor Law guardians were concerned, it was often a mere matter of chance whether it was they or the local health or lunacy or education authority who became responsible for a sick or feeble-minded person or a school-child. And as regards the aged, it was found that at the beginning of 1920, out of a total of 46,846 paupers over 70 in England and Wales, no less than 9,345 were old-age pensioners, two-thirds of them receiving outdoor relief and the other third in institutions.

The argument of the Maclean committee, therefore, like that of the royal commission, was based on administrative as well as on humanitarian grounds. The abolition of the Poor Law was

demanding in the interests both of the poor and of the public. The Maclean scheme was approved by the Govt. of the day, and by their successors. Pledges were given, and repeated, that a bill would be brought in so soon as the opportunity could be found. But the opportunity was remarkably elusive, and before long the moribund Poor Law had received an unexpected fillip.

The industrial depression, which began in 1920, led to an appalling increase of unemployment. The Unemployment Insurance Act and such relief works as were instituted soon proved inadequate to meet the situation, and armies of unemployed workers and their dependents had recourse to the guardians for money or the necessities of life. In Dec. 1920 the total number of persons in receipt of poor relief in England and Wales was 567,900. In the following Oct. it had risen to 1,494,000, and it went on rising till June 1922, when it reached the record of 1,837,980, or one in 21 of the whole population. Thereafter there was a gradual fall, but in June 1923 the figure was still over 1,250,000. Nor, of course, was this burden spread evenly over the 600 odd Unions; it fell heaviest on the most necessitous industrial areas. No less than 30 Poor Law Unions had one in 10, and Poplar and certain others one in five of their population in receipt of parish relief. The poor rates mounted to alarming heights, and in some districts the ratepayers were unable to meet the strain; the guardians had to borrow and thus saddle the rates with a heavy future load.

Two opposite views could be taken of this rush for relief. Defenders of the Poor Law urged that it proved the folly of the abolition policy. It was only the Poor Law, they said, that had enabled us to meet the crisis, and the Minister of Health spoke approvingly of the boards of guardians as "the sheet anchor of the nation." Others, however, passed a very different judgment. They did not blame the guardians; indeed, there was no question of blame, for the guardians were only performing their duty in preventing starvation. But they insisted that the Poor Law was never intended for such a task. Wholesale out-relief to the able-bodied was not among the objects of the Act of 1834; nor could even the most resolute opponent of reform honestly pretend that a board of guardians was a satisfactory unemployment authority, crisis or no crisis. And there was much criticism of the Govt., which, having failed to make proper provision for meeting the exceptional distress, had then, as it was alleged, deliberately encouraged this recourse to the Poor Law in order to divert the cost as far as possible from the taxes to the rates.

But the rising tide of unemployment led also to another startling development in the shape of a struggle between the Poplar board of guardians and the Ministry of Health over what was known as "Poplarism." The Poplar board, dominated by a Socialist majority, had long favoured the policy of giving what it regarded as adequate, and its critics as extravagant, outdoor relief. But in the circumstances of 1919 this policy meant an intolerable burden on the ratepayers. Efforts were made to get the Minister of Health to devise means for mitigating this burden in the poorer parishes, but in vain. The Poplar Borough Council then refused to collect the rates for the L.C.C. and certain other central bodies. Legal proceedings were taken, and the High Court ordered the collection of the rates. The Borough Council ignored the order, and 29 of its members were imprisoned for contempt of court. Following upon this a concession was made to the Poplar claim by the passage of the Local Authorities (Financial Provisions) Act, 1921, which provided for a large measure of equalisation in London, and in particular laid down that the cost of outdoor relief should be borne by the Metropolitan Common Poor Fund within the limits of a scale to be fixed by the minister.

The "Mond" scale, so called because Sir Alfred Mond was then Minister of Health, was issued in Jan. 1922. It did not satisfy the Poplar guardians, who now pressed for a loan to tide them over their immediate difficulties. A special inquiry was then instituted by the minister into the circumstances of Poplar. The report was unfavourable to the guardians, condemning their policy and declaring that by more economical methods they could save £100,000 a year. As they refused to

abandon their claim to administer relief at their discretion, the minister issued a peremptory Order, applying to the Poplar Union alone, and providing that no relief in excess of the "Mond" scale to an able-bodied person or any member of his family should be legal unless specially sanctioned by the minister. This order the Poplar guardians continued to defy, and so laid themselves open to surcharge. A curious complication was presently introduced by the Local Authorities (Emergency Provisions) Act, 1923, which apparently revoked automatically the "Mond scale," but left the special Poplar Order intact, though the two had been closely bound up together. This anomaly lasted till Feb. 1924, when the Poplar Order was rescinded. The Poplar guardians meanwhile were regularly surcharged by the auditor, but successive Ministers of Health ignored the surcharges, until at length, in Feb. 1924, Mr. Wheatley announced that he would take no action to enforce surcharges in respect of "illegal relief" given before the rescission of the Poplar Order. That was the end of this particular struggle, though it was not the end of the policy of high relief scales. Other boards of guardians continued to favour "Poplarism," and came into conflict from time to time with the Ministry of Health.

The history of the Poplar case illustrates some of the worst features of the Poor Law system—the problem of "necessitous areas," for example, the unsatisfactory relations between the central and the local authorities, and above all the unsuitability of the guardians to deal with unemployment. This indeed was recognised by the Poplar Board as well as by its critics, and drastic legislation was expected from the Labour Government. The Labour Govt., however, fell before it could prepare a bill, and the task of breaking up the Poor Law was left to its successors.

Towards the end of 1925 Mr. Neville Chamberlain, Minister of Health in the Conservative Govt., issued his "proposals for Poor Law reform," after successfully piloting through Parliament a Rating and Valuation bill which prepared the way for the abolition of the guardians. Under this statute the parish disappears as the valuation area, the board of guardians no longer appoints the assessment committee, and all the rating functions of the overseers of the poor are transferred to the town and district councils. The Act comes into force on April 1 1927.

The main points of Mr. Chamberlain's Poor Law scheme are:—

- (1) Boards of guardians to be abolished.
- (2) Registration of births, deaths and marriages to be transferred to electoral registration officers acting for counties and county boroughs.
- (3) The rest of their functions, and their property (including institutions), liabilities and staffs to be transferred to the county and county borough councils.
- (4) County borough councils to provide at their own discretion for the carrying out of the transferred duties.
- (5) The county council to be the supervising and controlling authority for all health purposes and to have complete responsibility for "home assistance" throughout the administrative county. The transferred duties to be carried out "through existing or new committees of the council, assisted where necessary by local sub-committees consisting of county councillors, or partly of county councillors and partly of representatives of the borough and district councils of the localities" (or of the metropolitan borough councils in London). But delegation to be allowed to borough and district councils (or metropolitan borough councils in London) of "any transferred service identical in kind with a service already administered by the borough or district council" (e.g., care of infancy and expectant or nursing mothers).
- (6) Relief to able-bodied persons to be limited and correlated with unemployment insurance.
- (7) The assigned revenue system to be abolished. Block grants fixed for a term of years to be paid in aid of transferred and existing health services and distributed to county and county borough councils on a basis of population qualified by a factor representing low ability to pay. The cost of delegated services to be borne by the borough or district councils to which they are delegated.

This scheme, it will be seen, is based in principle on the Maclean report. But it has certain differences of detail, some of them important. In particular, it gives a greater power to the counties, allowing no such autonomy as the Maclean report recommended to the larger non-county boroughs and urban districts. It also contemplates some special system of dealing with the able-bodied unemployed, though what that system is to be cannot be

discovered from the brief and obscure statement (see 6, ante) in which it is adumbrated. The whole scheme, however, was stated by the minister to be provisional; it was issued primarily for consideration and criticism by the local authorities and others concerned. There was no likelihood of a bill being passed before the session of 1927.

The number of persons in receipt of poor relief in England and Wales at the end of Dec. 1925 was 1,324,314 (222,494 in institutions and 1,101,820 relieved at home). This figure does not include lunatics in asylums, casuals or persons receiving medical relief only, who together amounted to about 119,000. The totals in previous years were:—

|      |           |      |           |
|------|-----------|------|-----------|
| 1913 | 632,242   | 1922 | 1,406,028 |
| 1919 | 483,148   | 1923 | 1,240,723 |
| 1920 | 567,909   | 1924 | 1,071,945 |
| 1921 | 1,375,982 |      |           |

(See Ministry of Health "Statement showing the Number of Persons in receipt of Poor Law Relief in England and Wales in the Quarter ending in Dec. 1925," 1926.)

The following table shows the total expenditure (other than out of loans) on all Poor Law services in England and Wales in the post-War period.

Year ending March 31:—

|      | £          |      | £          |
|------|------------|------|------------|
| 1919 | 18,424,000 | 1922 | 42,272,555 |
| 1920 | 23,501,000 | 1923 | 42,020,000 |
| 1921 | 31,925,000 | 1924 | 37,883,000 |
|      |            | 1925 | 36,500,000 |

Of the 1925 total of £36,500,000 about £31,000,000 was borne by the rates, as compared with £32,571,000 in 1923-4; £38,537,000 in 1922-3 and £12,078,000 in the year before the World War.

In Scotland, in May 1924, the total number of legal poor of all classes, including dependents, was 229,019. The great majority were on outdoor relief; 17,486 were insane, maintained in asylums, poorhouse wards or private dwellings. Of the sane, 11,091 (including nearly 1,000 children) were in the poorhouses, and the destitute able-bodied unemployed numbered 30,000. Scottish Poor Law expenditure for 1923-4 amounted to £4,370,609, as compared with £4,538,127 in 1922-3, £2,093,523 in 1919-20, and £1,609,538 in 1913-4. These totals include the amounts spent on relief of able-bodied unemployment, which were £1,286,654 in 1923-4 and £1,466,891 in 1922-3.

**POPE, JOHN RUSSELL** (1874– ), American architect, was born in New York City April 24 1874. He was educated at the College of the City of New York, and graduated at the School of Mines, Columbia University, in 1894. In 1895 he was fellow of the American Academy at Rome and in 1896-7 held the Schermerhorn travelling fellowship in architecture. In 1900 he attended the Ecole des Beaux Arts in Paris, and in the same year commenced practice in New York City. In addition to many private residences he designed the Scottish Rite Temple, Washington, D. C.; Plattsburg (N. Y.) City Hall; the Terminal Station, Richmond, Va.; the McDonough Memorial at Plattsburg; and the Lincoln Memorial at Hodgenville, Kentucky. He was chosen architect for the Roosevelt Memorial in Washington, D. C., and the Roosevelt Memorial in New York City.

**POPE, SIR WILLIAM JACKSON** (1870– ), British chemist, was born in London March 31 1870, and was educated at Finsbury technical college, and the central technical college, London. From 1897 to 1901 he was head of the chemistry department at the Goldsmith's Institute, and in 1901 he became professor of chemistry at the municipal school of technology at Manchester, occupying the chair of chemistry in the university there from

1905 to 1908. In 1908 he was appointed professor of chemistry at Cambridge, where he was later elected a fellow of Sydney Sussex College. Pope carried out much valuable research work on organic chemistry and crystallography, with particular reference to optical activity, and, conjointly with Barlow, on the relation between crystalline form and chemical constitution. During the World War he served on Lord Fisher's Admiralty Inventions Board (1915), and was conspicuous for his work on poison gases, and for the active assistance he gave to chemical industries. He was knighted in 1919, and was in addition the recipient of many British and foreign awards, including the Davy Medal of the Royal Society, to which he was elected, in 1914. His numerous scientific papers appear in various learned journals.

**POPPER, DAVID** (1846-1913), Bohemian violoncellist (see 22.91), died Aug. 7 1913.

**POPULATION** (see 22.92).—About two-thirds of the inhabitants of the world are now periodically enumerated by means of a census. Whenever a census is taken questions are asked regarding some or all of the following matters: age, sex, occupation, place of residence, religion and others. Thus, regarding two-thirds of the inhabitants of the world there is a considerable volume of information of a fair degree of accuracy. The questions asked vary considerably from country to country. Since information is nearly always required regarding age, sex and marital condition, the inhabitants of different countries, the population of which is periodically enumerated, can be compared in respect to these matters.

But with regard to the asking of questions concerning other matters much variation exists, and comparisons are often rendered impossible. There is no question regarding religion in the English census, for example, and comparisons in this respect between England and other countries where such information is collected are therefore not possible. For information regarding the remaining third of the world population it is necessary to rely upon estimates. No great degree of confidence can be placed upon these estimates, and a wide margin of error must be allowed for. Furthermore, estimates can only be made for the total population. It is impossible to estimate the distribution of the population in respect to age or sex, and as to this, therefore, for the remaining third of the world population there is no information at all.

The first step is to analyse and tabulate this information so as to throw light upon such points as it is desirable to investigate. The information contained in recent enumerations can be compared with that contained in former enumerations. The next step is to enquire how the population of any area comes to be what it is and how the changes found to have taken place between one enumeration and another have been brought about. This involves an examination of the facts regarding marriages, births, deaths and migration which are generally recorded annually for those areas in which a census is taken. From these registration statistics it is possible, for example, to throw light upon the proportion between the sexes as disclosed by the census figures. It can be shown that there is a certain proportion of male to female births and that the death-rate differs for males and females in each age period. In this manner an explanation is provided of the facts given by the enumeration. The attempt can then be made to push the explanation further back. The problem as to the cause of the difference in the proportion of male to female births can for instance be investigated. But such enquiries pass beyond the field of what is usually included in the study of the population problem, and attention in this article is confined to the study of the facts as disclosed by censuses and estimates and to the immediate explanations of these facts as far as registration statistics throw light upon them.

## I. WORLD POPULATION AND ITS DISTRIBUTION

*Geographical Distribution.*—Of the many estimates of the population of the world that have been made the best known are those of M. M. Levasseur and Bodio for the years 1880 and 1900 and of M. Bunle for 1920. Since the census figures and estimates used

in making these calculations were those available nearest the years 1880, 1900 and 1920 the totals given below should be read as estimates of the population "about" 1880, 1900 and 1920 respectively. Thus the British figures included in the 1920 estimate are those given in the census of 1921.

TABLE I. *Estimated Area and Population of the World*

| Region         | Area in thousands of square miles | Population in millions in |       |       | Density per square mile in 1920 |
|----------------|-----------------------------------|---------------------------|-------|-------|---------------------------------|
|                |                                   | 1880                      | 1900  | 1920  |                                 |
| Europe . . .   | 3,899                             | 347                       | 401   | 451   | 116.5                           |
| Africa . . .   | 11,766                            | 197                       | 135   | 132   | 11.0                            |
| Asia . . .     | 16,173                            | 789                       | 850   | 956   | 59.6                            |
| N. America . . | 9,891 <sup>1</sup>                | 80                        | 107   | 144   | 14.5                            |
| S. America . . | 7,096                             | 32                        | 43    | 67    | 9.3                             |
| Oceania . . .  | 4,231                             | 38                        | 52    | 69    | 16.3                            |
| Totals . . .   | 53,056                            | 1,483                     | 1,588 | 1,819 | ..                              |

<sup>1</sup> Including approximately 3,222,000 sq. m. of arctic and sub-arctic territories.

In compiling these estimates the Malay Islands have been included in Oceania, whereas in other estimates they are sometimes included in Asia. To what extent can these estimates be relied upon? No very high degree of accuracy can be attributed to the totals of the earlier estimates. As M. Bunle points out, while the areas of the continents given in the above table may be taken as approximately accurate, the 1920 figures for Africa and Asia and to a lesser extent for the other continents, with the exception of Europe, differ from those given by MM. Levasseur and Bodio when making the earlier estimates. The areas have of course not in fact changed, and the differences are due to more accurate recent measurements. It is evident that if the areas were not even known with accuracy when the earlier estimates of population were made, these latter estimates are likely to have exhibited a much larger margin of error. That the estimated population given in the above table for 1920, however, is not likely to be seriously in error may be deduced from the fact that it agrees fairly closely with other independent estimates. Thus the International Institute of Agriculture at Rome gives the estimated population of the world as 1,820 millions for 1921 and the Institut International de Statistique 1,791 millions for 1920 and 1,895 millions for 1924.

*The Various Continents.*—Considering the continents in turn, the figures for Europe and North America may be accepted as approximately accurate, though some doubt arises concerning the figures for Russia and Mexico. It is thus seen that whereas the population of Europe has increased by about 50,000,000 in each of the periods 1880–1900 and 1900–20, the population of North America has increased by about 25,000,000 in the first period and by about 37,000,000 in the second period. The difference between the two continents in this respect in the later period is partly to be explained by migration from the former to the latter and partly by the effects of the World War. The figures for Oceania are probably more accurate than those given for any of the other remaining areas. In twenty years the population appears to have increased about 30%, which is approximately the rate of growth found for the population of North America. While very considerable progress has been made during recent years in the enumeration of the inhabitants of certain South American countries, especially of Brazil, Argentina, Chili and Uruguay, there remains a large measure of doubt as to the present population of the continent. The figures for the earlier years are still more open to suspicion. There is no question but that the population of this continent has increased largely since 1906; it may be doubted, however, whether it has increased to the extent which these figures show.

The figures for Asia are still less trustworthy. For some areas of that continent, India and Japan for example, there are reliable figures. But for other areas, China in particular, the estimates vary widely. M. Bunle accepts the estimate of 445,000,000 for China, Manchuria and the Chinese dependencies made in connection with the Chinese postal administration for 1921. This estimate is among the highest, but it agrees closely with those of

the Chinese Maritime Customs for 1922 and of the China Continuation Committee for 1918. There are estimates as low as the 318,000,000 given by current books of reference. These low estimates have apparently been influenced by the census of 1910, which was a census of households and not of persons. Furthermore, the households were multiplied by different factors in different parts of the country to get the total number of persons—an obviously unsatisfactory method. Given this uncertainty

FIG. 1.—Chart showing the changes in the populations of certain selected countries from 1910 to 1924. The most marked features are the effect of the war upon the populations of the United Kingdom (which includes the area now called the Irish Free State), Germany, France and Italy; and the rapid increase in the populations of the United States and Japan.

regarding the population of China, it is evident, especially in view of the tendency to accept a higher estimate, that no reliance whatever can be placed upon the apparent growth in the population of Asia shown in the table as taking place between 1900 and 1920. The difference between the estimate for the population of Asia for these dates is less than the difference between the estimates of the population of China at the present day. Similarly, no confidence can be placed upon the apparent decrease in the population of Africa between 1880 and 1920. Estimates for the population of the Belgian Congo vary from 8,000,000 to 30,000,000. In large part the difference between the figures is due to the acceptance of lower estimates for the negro population. At the same time, parts of the continent have been ravaged by sleeping sickness and other diseases in late years and it is at least unlikely that there has been any increase in the population.

While it is not possible to obtain any accurate measurement of the proportion of the world population represented by the populations of the different continents at various dates and thus

to record the relative advance of the populations of some continents compared with others, it is possible to obtain a fairly accurate measurement of the changing proportion of the total population of Europe shown by various European countries. A similar calculation can be made for North and South America, though it would be misleading to take the figures back to so early a date as in Europe, since it is only of late years that the data have attained a reasonable degree of accuracy. The following table therefore shows the proportion which the population of the principal countries of Europe contributed to the total population in 1880, 1910 and 1920, and the proportion contributed by the principal countries of North and South America in 1910 and 1920.

TABLE II. *The Proportion of the Total Population of Europe (=100) and of America (=100) Contributed by Certain European and American Countries at Various Dates*

| Europe              |       |       |       | North and South America |       |       |
|---------------------|-------|-------|-------|-------------------------|-------|-------|
| Country             | 1880  | 1910  | 1920  | Country                 | 1910  | 1920  |
| England & Wales     | 7.77  | 8.06  | 8.38  | Argentina               | 3.93  | 4.14  |
| Scotland            | 1.12  | 1.06  | 1.08  | Brazil                  | 12.98 | 14.73 |
| Ireland             | 1.55  | .98   | .98   | Canada                  | 3.99  | 4.23  |
| France              | 11.20 | 8.76  | 8.67  | Chili                   | 1.80  | 1.81  |
| Germany             | 13.54 | 14.52 | 13.24 | Colombia                | 2.83  | 2.81  |
| Austria             | 6.63  | 6.38  | 1.42  | Cuba                    | 1.19  | 1.39  |
| Belgium             | 1.65  | 1.66  | 1.65  | Mexico                  | 8.40  | 6.68  |
| Hungary             | 4.71  | 4.67  | 1.77  | Peru                    | 2.49  | 2.40  |
| Italy               | 8.52  | 7.75  | 8.59  | United States           | 50.98 | 50.84 |
| Russia              | 25.82 | 29.13 | 22.50 | Venezuela               | 1.48  | 1.16  |
| All other countries | 17.49 | 17.03 | 31.72 | All other countries     | 9.93  | 9.81  |

Between 1880 and 1910 there were no changes in the frontiers of European countries, and the alterations in the relative positions of the various countries are due to varying rates of increase. The notable features are the decline in the position of France and the advance in the position of Russia. Between 1910 and 1920 there were large losses and large gains of territory in many countries. In addition, all European countries experienced an increased death-rate. Thus, in the case of the 1920 figures the changes due to varying rates of increase are overshadowed by the effects of the War. These effects have been remarkable. It is noticeable that France, in spite of an increase in territory, has not quite maintained her position, and that Germany, in spite of a large decrease in territory, has suffered comparatively little. Austria and Hungary now contribute less than 2% each to the population of Europe. The figures for North and South America are interesting in that they show that the various countries tend to maintain their relative position.

*Racial Distribution.*—It is necessary to exercise the greatest caution in the use of the term "race." If by racial groups are meant groups of men exhibiting in common certain inherited character differences, then we may legitimately employ the term. There are groups of men exhibiting in common certain inherited characteristics in respect of hair, pigmentation and other physical features, and it may be asked what proportion of the population of the world falls into each of the larger groups. To this question no satisfactory answer can be returned. Not only in South America, for example, is the total population not accurately known but trustworthy data as to the proportion which each racial group, Caucasian, Negroid and Amerindian, contributes respectively to the estimated total are wholly lacking. The same applies to Asia and Africa. An estimate has been made by Sir Leo Chiozza Money of the total numbers of the so-called "white race," an element of the Caucasian group formerly more or less confined to Europe. He finds that out of an estimated world population of 1,852 millions in 1921, there were 603,000,000 belonging to this white element, that is to say, rather less than a third of the total world population. He also finds that of the 603,000,000 about 117,000,000, or less than a fifth, are of British stock. If these 600,000,000 whites are subtracted from the total world population, leaving some 1,250 millions to be distributed among the remaining racial groups, then it may be very roughly estimated that about half this number belong to the Mongoloid

racial group, while two-thirds of the balance belong to the non-White branch of the Caucasian group and one-third to the Negroid racial group.

It thus appears that the white branch of the Caucasian racial group and the Mongoloid group between them account for about two-thirds of the population of the world. In the absence of accurate information as to the constitution of the population of the world to-day it is clearly impossible to discover whether the different racial groups are maintaining their relative positions or whether one or more groups have improved their relative positions since 1900 or 1880. It can only be said that the white element of the Caucasian group, which was during the greater part of the last century considerably improving its position, is in any case not now doing so in the same ratio if indeed it is improving it at all.

## II. ECONOMIC DISTRIBUTION

*Density.*—In Table I. is shown the density per sq. m. of the population of each continent. The average density of population for the whole land area included in the table is 34 per sq. mile. From this table the uninhabited continent of Antarctica is excluded. It should be noted that no deduction has been made on account of the barren and almost uninhabitable areas which are included within every other continent. The inclusion of these areas tells least against Europe and most against North America. Thus Greenland, Alaska, the Northwest territories of Canada, Labrador and the Arctic Islands, cover an area of approximately 3,222,000 sq. m., and contain a population amounting only to about 113,000. If these areas are excluded the average density of population in the rest of North America rises from about 14 to about 22 per sq. m. and in the world as a whole to about 36. Taking the figures as they are, it appears that Europe and Asia are the most crowded continents, Europe being about twice as densely peopled as Asia. The remaining continents are, relatively speaking, empty.

Among countries and areas which are regarded as distinct units from the point of view of political organisation, Barbados is the most densely populated, having (in 1921) 952 per sq. m., while Java comes next with (in 1920) 689 per sq. mile. Belgium is the most densely populated among European countries with 635 per sq. m. (in 1920), while Great Britain has 482 per sq. m. (in 1921). It is worthy of notice that England and Wales have a density of 649 per sq. m. (in 1921), and are therefore more densely peopled than Belgium. Such comparisons can be widely extended and up to a point are informative. It should be remembered that they may also be very misleading. The area of Egypt is, for example, 383,000 sq. m., and the total population amounts to 12,750,000, giving an average density of 33 per sq. mile. But the population of Egypt is almost wholly confined to the valley and delta of the Nile, the areas of which contain 12,023 sq. m., giving a density of 1,061 per sq. m. of the inhabited area. So, too, the figure of 1.83 per sq. m. for the continent of Australia misrepresents the facts. A considerable proportion of the continent is uninhabitable, and if this part was excluded from the calculation the density per sq. m. would be appreciably raised.

The figures for density given above fail to bring out certain important facts. An examination of the map of the world showing density of population without regard to political boundaries makes it at once apparent that there are three densely populated regions of no great size. The first region is that part of Europe which lies south of the parallel 60° north latitude. The second is that made up of the greater part of India and Ceylon; the third includes Japan, the greater part of Manchuria and China and a strip along the coast of Tonking. It may be roughly estimated that the population of these regions amounts to 440,000,000, 480,000,000 and 300,000,000 and the areas to 2,900,000, 2,000,000 and 1,200,000 sq. m. respectively. We thus find over 1,200 million people living on about 6,000,000 sq. m., or in other words about two-thirds of the world population living on about one-eighth of the habitable area. There are four other very much smaller regions which are densely peopled, the New England area of the United States, the Nile valley and delta, the tip of the Malay Peninsula and Java.

*Urbanisation.*—As seen above, figures for average density may be misleading if within the area of a country or region there

are large barren tracts. But even if they are not misleading, or if calculations are made to correct the misleading impression otherwise given, such figures fail in themselves to provide an adequate picture of the conditions under which the inhabitants of an area are living unless they are supplemented by facts throwing light upon the degree of urbanisation.

It is not an easy matter to obtain a measure of urbanisation. The census returns of most countries classify the population into urban and rural, but while these figures are useful for comparing changes in the same country between two dates, they are of little use when comparing two countries. This is so because the classification is based upon very different methods in different countries. Thus, owing to differences in local government between England and Scotland, the figures giving the percentages of urban dwellers out of the total populations are not comparable. Again, those officially classed as urban dwellers often live under what to most people would appear as rural conditions. English urban dwellers include, for instance, according to the official classification, those who live in the areas of urban district councils and, as is well known, to live in such an area is often regarded as having escaped from a town. The best method is perhaps to note, in the table below, the percentage of the total population living in towns having a population of 100,000 and over.

TABLE III. *Density of Population and Urbanisation: 1920*

| Country                                   | Population per square mile | Percentage of population living in towns having 100,000 inhabitants and over |
|-------------------------------------------|----------------------------|------------------------------------------------------------------------------|
| Egypt (cultivated area only)              | 1,061                      | 9.9                                                                          |
| England and Wales                         | 649                        | 38.8                                                                         |
| Japan                                     | 484                        | 12.1                                                                         |
| Italy                                     | 329                        | 13.7                                                                         |
| Germany                                   | 319                        | 23.7                                                                         |
| China                                     | 274                        | 2.2                                                                          |
| France                                    | 184                        | 15.0                                                                         |
| India                                     | 177                        | 2.6                                                                          |
| Russia (in Europe)                        | 57                         | 4.0                                                                          |
| United States                             | 35                         | 25.7                                                                         |
| Canada (excluding North West territories) | 3                          | 18.9                                                                         |
| Australia                                 | 1.83                       | 41.3                                                                         |

This table must be interpreted with caution. The method of calculating urbanisation here adopted is not perfect. The urbanisation of Australia, for example, is exaggerated. The urban

population of Australia is concentrated in five large towns and there are few towns of relatively small size. If 50,000 instead of 100,000 was taken as the lower limit, Australia would come out as relatively less urbanised than under the present method of calculating urbanisation. Allowing for its defects, the table does show that there is little association between density of population and urbanisation. Densely populated countries may or may not have a high degree of urbanisation; Australia is an example of a sparsely peopled country with a high degree of urbanisation. Further examination of the table shows that urbanisation goes with industrialisation rather than with density. In other words, a high degree of density without industrialisation does not lead to urbanisation, whereas urbanisation can go a long way where industrialisation prevails, even though the population is sparse. The countries which have a high degree of density without urbanisation are those such as China, India and Egypt, where intensive agriculture is practised. Density thus accompanies intensive agriculture and may also be attained under industrial condition.

There were, in 1920, 16 towns with a population of over 1,000,000 apiece. Of them six were in Europe, five in Asia, three in North America and two in South America. One remarkable result of the War has been the decline in the population of certain great towns. Thus between 1910 and 1920 Moscow decreased from 1,481 to 1,028, Leningrad from 1,907 to 706 and Vienna from 2,030 to 1,841 millions.

### III. DISTRIBUTION BY SEX AND AGE

*Sex.*—It is a familiar fact that in Great Britain and most European countries females outnumber males. The extent to which this is the case is shown in Tables IV. and IV.-A. The tables show the number of females to 1,000 males in certain European countries about the years 1910 and 1920 and in certain non-European countries about the year 1920.

The European countries include all the larger ones, among them Russia, Germany and France, and most of the smaller ones. The newer countries *e.g.*, Czechoslovakia and Yugoslavia are not included, as in their case there is no information about conditions in 1910. Wales, as usual in such cases, is treated with England, but separate figures are given for Scotland. The non-European countries are the United States, Canada, Australia, India, Japan, South Africa and Egypt, for all of which the necessary statistics are available.

As regards the figures for the European countries for which there is information at both dates, it is seen that in the case of the countries neutral during the War there has been little change on the whole in the proportion between the sexes, whereas in the case of belligerent countries the former considerable excess of females was increased. Belligerent countries are therefore abnormal in respect of the existing large excess of females, and the increased disparity between the sexes is due to deaths of males during the War. The exceptional case of the lately belligerent countries may be thus left out of account, and the proportions about 1910 taken as more normal for European conditions. It next appears that most European countries are strongly contrasted with those extra-European countries for which figures are given. The latter show a deficiency of females.

TABLE IV.-A. *Proportion of the Sexes Living and at Birth in Certain Non-European Countries about 1920*

| Country                   | No. of females to 1,000 males about 1920 | No. of male births to 1,000 female births about 1920 |           |       |
|---------------------------|------------------------------------------|------------------------------------------------------|-----------|-------|
|                           |                                          | Born living                                          | Born dead | Total |
| U.S.A.                    | 960                                      | ..                                                   | ..        | ..    |
| Canada                    | 940                                      | 1065                                                 | 1402      | 1075  |
| Egypt                     | 997                                      | 1093                                                 | 1512      | 1097  |
| South Africa <sup>1</sup> | 943                                      | 1076                                                 | ..        | ..    |
| Japan                     | 979                                      | 1045                                                 | 1176      | 1053  |

| Japan 1918                      | 125        |             | 88   |       | 81    |       | 118   |       | 97          |       |       |                   |  |  |

The influence of the decline of the birth-rate is best seen in the case of England and Scotland when the age distribution of 1911 is compared with that of 1921. The number of those under five years of age has decreased, while there has been a marked increase in the number of those over 45. If the number of those of 65 years and over

[illegible]

is considered, it is found that there were in every thousand of the population 52 in this age group in 1911 and 60 in 1921. Since persons of these ages are for the most part dependent upon others for their support, it will be seen how the burden increases which a declining birth-rate places upon the producing section of the community. There is a close similarity between the figures for the United States and Australia. Both countries have experienced the influence of immigration and of a declining birth-rate. The figures for France and Germany are pre-War figures. The birth-rate of France has long been steady, and it is towards some such age distribution as that now seen in France that the age distribution in England is tending. Figures for the whole of Germany since the War are not available but, in so far as Prussia is representative of German conditions, the influence of the decline of the birth-rate upon the age distribution can also be seen in Germany. In the last two lines of the table the figures for Japan in 1918 and for England in 1881 have been set out, and it is evident that the present constitution of the Japanese population in respect to age closely resembles that of the population of England and Wales 40 years ago.

How do these differences arise? If the birth-rate and the death-rate remained constant in a country over a period of years and if there was no migration, the population would become and remain distributed according to age in a certain fashion. It is because the birth-rate, death-rate and migration rate change in the same country as between one period and another and because they do not change similarly in different countries that there are differences in age distribution as between the population of the same country at different times and between different countries at the same time. The case of England and Wales may be taken as an example. During the last century the death-rate declined, and principally as a result of this the population rapidly increased. The population of England and Wales in 1861 was 20,066,224, and in 1921 was 37,886,699, and in consequence persons of 60 years of age and over are the remnant of a population little more than half as large as the existing population.

TABLE VII. *Mean Age at Marriage of Those not Previously Married*

| Country               | 1876-85 |      | 1886-95 |      | 1896-1905 |      | 1906-10 |      | 1911-15 |      |
|-----------------------|---------|------|---------|------|-----------|------|---------|------|---------|------|
|                       | M.      | F.   | M.      | F.   | M.        | F.   | M.      | F.   | M.      | F.   |
| England and Wales . . | 25.9    | 24.4 | 26.4    | 24.9 | 26.8      | 25.3 | 27.2    | 25.6 | 27.4    | 25.7 |
| France . .            | 28.0    | 23.9 | 27.9    | 23.4 | 27.9      | 23.6 | 28.0    | 23.7 | ..      | ..   |
| Germany . .           | ..      | ..   | ..      | ..   | ..        | ..   | ..      | ..   | 27.4    | 24.7 |
| Holland . .           | 28.3    | 26.5 | 28.0    | 26.1 | 27.9      | 25.9 | 27.7    | 25.9 | 27.6    | 25.8 |
| Italy . .             | ..      | ..   | ..      | ..   | 27.4      | 23.9 | 27.1    | 23.6 | 27.2    | 23.6 |
| Scotland . .          | ..      | ..   | ..      | ..   | 27.6      | 25.6 | 27.8    | 25.8 | 27.8    | 25.8 |
| Sweden . .            | 28.7    | 27.1 | 28.7    | 27.0 | 28.6      | 26.6 | 28.7    | 26.3 | 28.8    | 26.4 |
| Switzerland .         | ..      | ..   | 28.5    | 26.1 | 28.4      | 26.0 | 28.3    | 25.8 | ..      | ..   |

But the birth-rate has been decreasing for half a century. It can be calculated that, if the birth-rate remains at about its present level and if the death-rate does not change significantly, the population will cease to increase within two decades, and will remain approximately stable. Under these circumstances the age distribution would become stabilised. This example explains the differences between the age distribution in France and England, since in the former country there has been little change for some years, with the result that there is a larger proportion of old persons than in this country. Migration largely explains the high proportion of younger persons in the Dominions, and similarly explains the deficiency of such persons in Ireland.

#### IV. MARRIAGE, BIRTH AND DEATH RATES

*Marriage.*—The age distribution of the population is given in the census returns, but the attempt to interpret changes in the age distribution leads to the employment of data regarding birth-rates and death-rates which are obtained from registration statistics. Similarly, certain data regarding marriage can be obtained from the census returns, but for the interpretation of these figures recourse must be had to registration statistics of marriage. One method of representing the facts is to give the number of married persons per 1,000 of the population. This method is open to the objection that, since the age distribution in the same country at different times and in different countries at the same time is not the same, figures are not comparable. Another method is to give the number of married persons per 10,000 of the marriageable population. The marriageable population is defined as consisting of all males 18 years of age and over and of all females of 15 years of age and over, excluding only those of either sex who are married. This latter method is to be preferred, though it is applicable only to countries with European standards and habits. It fails to represent, for instance, the true condition of things in India, where in 1921 there were 110,-

684 boys and 218,463 girls married under five years of age and 757,405 boys and 2,016,687 girls married between the ages of five and 10. Further, there were over 2,000,000 boys and 6,000,000 girls married between the ages of 10 and 14.

The table brings out the fact that the different countries vary in a striking manner in respect of the marriage rate thus calculated. There is a group of Western European countries where the rate tends to exceed 500, and a group of Eastern European countries where it approaches or exceeds 1,000. The rate has not tended to vary widely in each country during the period to which the figures apply. Generally speaking, countries that had a high rate around 1876 have maintained that rate, and countries with a low rate have maintained a low rate. It has long been known that the marriage rate in England tends to vary in the same direction as the price of wheat, the value of exports, and such indices of prosperity as the amount cleared at the Bankers' Clearing House per head of population. But these variations are not large, being in the same direction but not in the same degree as the changes in the indices of national prosperity.

Another matter of considerable importance is the mean age at marriage. In giving figures for the mean age at marriage it is best to omit marriages of widowed and divorced persons. It is the age at marriage of bachelors and spinsters that is of importance, and the facts as to the age at marriage of these persons are obscured if other marriages are taken into account. The mean age at marriage is of course not the same as the most usual age at marriage. Thus, the mean age at marriage in England and Wales in 1920 was not far from 28 for bachelors and 26 for spinsters, whereas the most common ages at marriage in the same year were 24 for men and 21 for women.

The table shows that the mean age at marriage is very similar in all countries for which figures are given. The age for men is a little over 27, while that for women varies from 23-26. Furthermore, there has been but little change in the mean age for fifty years: in France it has remained practically the same; in England and Wales there has been a tendency towards postponement; whereas in Holland the tendency has been the other way.

*Births, Deaths and Natural Increase.*—The census provides no information as to births and deaths. We are here dependent upon registration statistics. The most usual method of recording the birth-rate and death-rate is to give the number of births and the number of deaths per 1,000 of the population in any year. For certain purposes this method is open to objection. Unless the age distribution is known and allowed for, it is clear that these crude rates are no measure of the true fertility of married women or of the health and vitality of the population. But these crude rates serve a useful purpose. The difference between the rates represents the natural increase or decrease per 1,000 of the population as the case may be. This natural increase or decrease is an important fact in gauging the actual position of any country, though further analysis is required in order to throw light upon the manner in which the natural increase or decrease is brought about.

The crude birth-rates varied from 40.3 in Bulgaria to 19.19 in Switzerland during the period under review. The crude death-rates varied from 33.6 in Greenland to 9.1 in New Zealand. The highest natural increase was in Bulgaria and the lowest in France. While it so happens that Bulgaria had the highest crude birth-rate and the highest natural increase, a glance at the table will show that there is in general no correspondence between a high birth-rate and a large natural increase. Thus Greenland, with a birth-rate nearly as high as Bulgaria, had, next to France and Austria, the lowest natural increase. The table shows that countries with a high birth-rate often have a high death-rate and thus do not exhibit a large natural

TABLE VIII. *Mean Annual Number of Marriages per 10,000 Marriageable Persons*

| Country                     | Period  | Proportion | Period    | Proportion |

increase. The association of a high birth-rate with a high death-rate has been much discussed. What the precise nature of the association may be is not clear; to some extent, no doubt, a high birth-rate renders the care of children by the mother more difficult, and to this extent a high birth-rate may be said to cause a high death-rate. At the same time, however, a high death-rate tends to call forth the birth of more children to fill the vacant places, and to this extent the relation is reversed and a high death-rate is the cause of a high birth-rate. It is worthy of note that, as a comparison of Table VIII. with Table IX. shows, those countries with a high birth-rate are in general also those with a high marriage rate.

But the most interesting and important fact which emerges from Table IX. is that the same natural increase is found in countries which have widely divergent birth and death-rates. Thus, the United States and Japan had both the same natural increase for the periods under review, but, whereas the former had relatively low birth and death-rates, the latter had high rates. The contrast is even more striking between New Zealand, with its low rates and natural increase and such a country as Ceylon, with a death-rate nearly as high as its high birth-rate and in consequence a low natural increase. Apart from the question whether increase is desirable and if so to what extent, it is clear that, if there is to be increase at all in any country, those conditions are to be preferred by which it is attained by a margin between a low birth-rate and a low death-rate rather than between a high birth-rate and a high death-rate.

TABLE IX. *Birth-rates, Death-rates and Natural Increase*

| Country                     | Period  | Crude birth-rate | Crude death-rate | Natural increase |
|-----------------------------|---------|------------------|------------------|------------------|
| Australia . . . . .         | 1919-24 | 24.6             | 10.4             | 14.2             |
| Austria . . . . .           | 1919-23 | 21.9             | 17.9             | 4.0              |
| Belgium . . . . .           | 1919-24 | 20.5             | 14.0             | 6.5              |
| Bulgaria . . . . .          | 1920-1  | 40.3             | 21.7             | 18.6             |
| Canada . . . . .            | 1920-4  | 25.3             | 10.9             | 14.4             |
| Ceylon . . . . .            | 1919-23 | 38.6             | 31.6             | 7.0              |
| Chili . . . . .             | 1919-24 | 39.7             | 32.6             | 7.1              |
| Denmark . . . . .           | 1919-24 | 22.9             | 11.8             | 11.1             |
| England and Wales . . . . . | 1919-24 | 21.0             | 12.5             | 8.5              |
| Egypt . . . . .             | 1919-23 | 41.6             | 26.6             | 15.0             |
| France . . . . .            | 1920-4  | 20.0             | 17.4             | 2.6              |
| Germany . . . . .           | 1919-24 | 23.5             | 14.8             | 8.7              |
| Greenland . . . . .         | 1919-22 | 38.7             | 33.6             | 5.1              |
| Holland . . . . .           | 1919-24 | 26.6             | 11.4             | 15.2             |
| Hungary . . . . .           | 1919-24 | 29.9             | 20.9             | 9.0              |
| Italy . . . . .             | 1919-23 | 27.3             | 17.0             | 10.3             |
| Japan . . . . .             | 1919-22 | 34.7             | 23.6             | 11.1             |
| New Zealand . . . . .       | 1919-24 | 23.0             | 9.1              | 13.9             |
| Norway . . . . .            | 1919-24 | 23.7             | 12.2             | 11.5             |
| Philippines . . . . .       | 1921-3  | 32.8             | 19.0             | 13.8             |
| Rumania . . . . .           | 1919-22 | 32.9             | 22.9             | 10.0             |
| Scotland . . . . .          | 1919-24 | 23.9             | 14.4             | 9.5              |
| South Africa . . . . .      | 1919-24 | 27.5             | 10.4             | 17.1             |
| Spain . . . . .             | 1919-23 | 29.8             | 21.8             | 8.0              |
| Sweden . . . . .            | 1919-24 | 20.3             | 12.8             | 7.5              |
| Switzerland . . . . .       | 1919-23 | 19.9             | 13.2             | 6.7              |
| U.S.A. . . . .              | 1919-23 | 23.8             | 12.7             | 11.1             |
| Uruguay . . . . .           | 1919-23 | 26.6             | 12.2             | 14.4             |

While natural increase is an important fact, it should not be taken at its face value. It should not be assumed, for example, that a given rate of natural increase will continue in any country, even if the true

fertility of married women and true mortality of the population remain at their existing strengths. This is so because the crude rates are imperfect measures of fertility and mortality. The crude birth-rate is the number born in any year per 1,000 of the population. In order to get a measure of true fertility it is clearly necessary to relate the births to the wives of child-bearing age in the population. In this manner the crude birth-rate can be "corrected." Newsholme gives the following example of using this method of correction. In Ireland, the crude birth-rate was 24.5 in 1881 as compared with 33.9 in England and Wales, and 23.1 in 1901 as compared with 28.4. When these crude rates are corrected they become for Ireland 35.2 in 1881 and 36.1 in 1901, and for England and Wales 34.7 in 1881 and 28.4 in 1901. Thus, the true fertility in Ireland was in fact as high as that in England and Wales in 1881 and much higher in 1901. The explanation of the remarkable differences between the two countries lies in the fact that, whereas in England in 1901 the number of females aged 15 to 45 per 1,000 of the total population was 250 and in Ireland 235, the wives at ages 15 to 45 in England formed 46.8% and in Ireland only 32.5% of the females at the same age. In addition to the importance which these corrections have as throwing light upon the true fertility of a population, they are also relevant to the problem of natural increase.

Let us take the case of England and Wales as an example of this fact. The figures show that there is still a considerable natural increase. It is, of course, true that, if the crude birth and death-rates remain unchanged, the population will continue to increase. It is popularly supposed that these rates represent the true fertility and mortality of the population. As shown above, this is not so. The true fertility and mortality of the population can be calculated, and it can be shown that, if the true fertility and mortality of the population remain as they now are, the crude rates will change until there is no gap between them. In other words, the true fertility and mortality of the population remaining as they now are, natural increase will become negligible in two decades and will later disappear.

The explanation of this paradoxical result is as follows: The age distribution in England and Wales is peculiar in that there is a relatively small number of persons in the older age groups. As a result of the decline in the birth-rate, the relative number of these older persons will increase and in consequence the death-rate will increase though the true mortality remains the same. The considerable natural increase now shown is, therefore, illusory, and will disappear unless there is a marked decrease in the true mortality or an increase in the true fertility. Should there continue to be a decrease in the true fertility as is in progress at present, then there will be a cessation of natural increase at a still earlier date.

*The Decline in the English Birth-rate.*—The crude birth-rate in England and Wales was 33.5 for the period 1871-5 and has declined to 18.8 in 1924. The decline has been in evidence in most European countries and in countries peopled by persons of European descent, though it usually began later than in England. Enough has been said above to show that these crude rates require interpretation. The decline in the crude birth-rate might be due to a decrease in the number of marriages, to a decrease in the proportion of women of child-bearing age, or to a decrease in the number of children born to married women of child-bearing age. A reference to Table VIII. shows that, while there are notable differences between different countries as regards frequency of marriage, there has been for 50 years little change in this respect in different countries. In other words, the decline in the birth-rate is not explained by a decline in the frequency of marriage.

Table VII. shows that in some countries there has been a tendency towards postponement of marriage, notably in England, but not in others. Now since the decline in the crude birth-rate is almost equally well marked in countries where there has been no postponement, the inference is that some factor or factors other than postponement of marriage must have played the principal part. But in England postponement has not been a negligible factor. It has had the effect not so much of decreasing the proportion of married women who are of child-bearing age as of decreasing the proportion of married women who are of the most reproductive ages. Thus of 1,000 wives under 45 there were in 1901, 593 under 35 and in 1921, 535 under 35. Nevertheless, in England, as elsewhere, the chief cause of the decline has been

the fewer number of children born to women of child-bearing age after making allowances for the smaller proportion among them of women of the most reproductive ages.

The problem is thus shifted to an inquiry into the reason for this declining fertility of married women of reproductive ages. Many suggested explanations can be shown to be inadmissible. In particular, it has been suggested that there has been a decline in reproductive capacity. Now reproductive capacity is a biological characteristic, and there are no biological grounds for suspecting any such change. Further, had any such change taken place it is only reasonable to imagine that it would have affected all sections of the population alike. But it is well known that it has not equally affected all sections, the birth-rate of the so-called upper classes having declined to a far greater extent than that of the so-called lower classes. By a process of exclusion the position is reached that the cause of the decline is to be sought in a change of habits. There is naturally but little direct evidence of such a change but there is an overwhelming amount of evidence that a change of habits has been advocated in the shape of the adoption of birth control methods. It is only reasonable to suppose that as a result of this propaganda birth control (*q.v.*) has been put into practice on a wide scale in many countries and that the decline of the birth-rate finds here its chief explanation. (A. M. C. S.)

**PORT ELIZABETH**, S. Africa (*see* 22.112), had a population (1911) of 37,063, and (1921) of 46,834, of whom 23,935 were whites, mostly of British descent. It is the third port of the Union, a centre for the wool and ostrich feather trade, and imports general merchandise for a wide area. Among modern buildings are the Provincial Hospital, the Grey Institute Boys' High School, and the Grand Theatre, the last in Main street. A breakwater intended to be 8,500 ft. long, part of a scheme to provide a completely sheltered harbour, was in 1925 under construction at the Dom Pedro jetty. In 1913 the tonnage of ships entering the port was 2,064,000. There was a marked fall thereafter which reached its lowest point (445,000 tonnage) in 1918. By 1923 the standard of 1913 had been, however, surpassed, the tonnage being 2,143,000. In that year the cargo handled at the port was 421,000 tons. The average value of imports, 1910-4, was £8,856,000, of exports £3,679,000. In 1923 the figures were, imports £12,519,000; exports £6,381,000.

**PORT ENGINEERING** (*see* HARBOUR, 12.935; DOCK, 8.353; BREAKWATER, 4.475; JETTY, 15.359; PIER, 20.588; RIVER and CANAL ENGINEERING).—Since 1910 important developments have taken place in many parts of the world to keep pace with the advance of engineering science, and particularly with the increase in the dimensions of shipping which was so marked in the 10 years preceding the World War.

#### THE DIMENSIONS OF SHIPPING

In 1910 the largest merchant ship afloat was the "Mauretania," of 30,696 gross tons, 762 ft. in length between perpendiculars, and 88 ft. beam; but, excluding transatlantic liners, the largest cargo-carrying ship did not exceed 13,000 tons. In 1914 merchant ships far exceeding the dimensions of the "Mauretania" were either afloat or under construction. Harbour authorities, not only of those ports which accommodated the great transatlantic liners but in many other parts of the world, were engaged in increasing their facilities to serve shipping of far larger dimensions than any which had hitherto used their navigable waters. During the War period harbour development throughout the world was arrested and confined largely to works of a nature essential to the objects of the belligerents.

Since 1914 no ships of greater dimensions than those built or

building at that date have been laid down and it is unlikely that there will be any marked increase in the maximum dimensions of transatlantic liners; the dimensions of the "Majestic" (ex. "Bismarck"), claimed to be the largest now (1926) afloat, and completed in 1921, being 56,551 gross tons, 915½ ft. length between perpendiculars, and 100.1 ft. beam. This vessel, when fully loaded, had a draught of 38.9 feet. On the other hand, a considerable increase seems likely in the number of cargo-carrying ships of large capacity. In 1910 general cargo vessels of over 10,000 gross tons were rare. Ships of this class up to 600 ft. in length, 72 ft. beam and 18,000 to 20,000 tons gross were not uncommon in 1926.

**Depth of Water.**—The deepening and widening of the Suez Canal enabled ships of the largest class to trade with Eastern ports. The canal has now been deepened throughout to 12 metres, and ships drawing 33 ft. pass through it. It is intended to provide for a draught of 35 feet. Concurrently with the deepening and widening of the Suez Canal, the more important ports of the Far East have been developed with the object of accommodating the largest ship capable of passing through it. The opening in 1914 of the Panama Canal, having a navigable depth of 40 ft., also had an important bearing on the development of harbours in the Far East and on the Pacific coasts of America. The general result is that whereas in 1910 a navigable depth of 30 ft. was considered ample for practically all requirements, a depth of 35 ft. is regarded essential in harbours of the first class, and in special cases even greater depths are aimed at.

**Effect of Depth on Cost.**—The cost of constructing port works in general shows an increase approximately proportional to the ratios of the cubes of the draughts of the largest ships for which they are designed.<sup>1</sup> The provision of port accommodation for shipping of the largest class is important from the point of view of finance and may become one of balance between the relative economy of ships of large draught and cargo capacity and the capital cost of port construction.

#### MATERIALS AND EQUIPMENT

**Materials of Construction.**—There has been no radical change in the nature of the materials used for the construction of port works since 1910, although reinforced concrete (*see* FERRO-CONCRETE) has been increasingly used in building jetties, wharves and other sea works. Rapid-setting aluminous cement was introduced on the Continent during the period under review, and its employment in Great Britain is extending, but its suitability for use in sea water had not been fully tested by the lapse of time. The use of Portland cement concrete for all kinds of port construction, quay walls, docks, breakwaters, etc., became universal, and its cheapness in comparison with the cost of dressed stone in the large majority of situations restricted the employment of the latter for such purposes as copings, sills, altar courses, etc. As an example of this change in practice the Rosyth dockyard may be mentioned. Practically all British Admiralty docks built prior to 1910 are faced throughout, or at any rate on all important surfaces, with dressed stone, usually granite. In the case of Rosyth, however, the quay and dock walls are faced with granolithic concrete, dressed granite being used only for copings, quoins, sills and in similar positions. The use of greenheart for the construction of dock gates gave place to mild steel, largely owing to the high cost of suitable timber in comparison with steel work.

**Mechanical Equipment of Docks.**—The most marked change in port engineering, apart from the increase in dimensions, is in connection with the mechanical equipment of docks and the provision of storage and traffic facilities. The use of electric power for cranes and other mechanical appliances is almost universal, and even in ports where hydraulic power is available electric appliances are installed side by side with hydraulic equipment. Hydraulic power presents undoubted advantages for operating gate-opening machinery, coal hoists and some other forms of dock equipment, but the adaptability and flexibility of electric power led to its general adoption. The mechanical handling of cargoes has made enormous strides. Elaborate and costly plants for storing, loading and discharging grain, chilled meat, coal, ores and oil in bulk have been established at ports in all parts of the world where such cargoes are dealt with in considerable quantities. The equipment of warehouses and transit sheds with electrically operated cranes, run-ways, loaders, conveyers and hoists is general, and high-speed electric cargo cranes are provided on a large scale at most European and North American ports, although in the Far East cargo is largely discharged by means of ship's derricks. Floating and fixed cranes of great capacity for lifting exceptional loads are common. Many floating cranes, lifting 250 tons, are in use; and one at least in America, a fixed crane at the Philadelphia Navy Yard, was capable of lifting 350 tons.

#### BREAKWATERS AND HARBOURS

**Breakwaters.**—In 1910 the greatest depth of water in which a breakwater structure had been founded was probably at Naples, where the outer portion of the San Vincenzo breakwater was constructed at a depth of about 120 ft. below mean sea-level. The outer portions of the Valparaiso breakwater,<sup>2</sup> built 1912-21, were founded at

<sup>1</sup> See L. H. Saville, *XIIIth International Congress on Navigation* (London, 1923).

<sup>2</sup> *Proc. Inst. of C. E.*, vol. 214 (1921-2).

FIG. 1.—Valparaiso Breakwater. FIG. 2.—Dublin Quay Wall. Floated Monolith of reinforced concrete.

a depth of 147 ft. below mean sea-level, and an extension 2,300 ft. in length, was to have its termination in a depth of about 180 feet. The breakwater is of composite construction, the inner portion consisting of concrete blocks set on a submerged rubble stone mound, and the outer portion (fig. 1) of reinforced concrete caisson monoliths, which were floated over and sunk upon a rubble mound (with sand core), the surface of which is at a level of 46 ft. below mean sea-level. These monoliths are the largest which had been hitherto constructed in such a situation, each measuring 20 metres long by 16 metres wide and 15 metres in height, and were, after sinking, filled in with mass concrete. The monoliths are surmounted by a mass concrete superstructure carried to a height of 7.5 metres above mean sea-level. The use of concrete monoliths in breakwater and pier construction has become general. Reinforced concrete caissons, floated into position and filled in after sinking with mass concrete, have been utilised both for the construction of superstructures resting on rubble mounds and, less frequently, as monoliths resting on the sea bed. Other examples of the former are the Galleira mole at Genoa and the extensions of the breakwater at Naples. The latter system was employed in the construction of some of the Heligoland moles demolished after the War.

The breakwater at Fishguard, constructed by the Great Western Railway Co. between 1900 and 1918, is an interesting example of a composite breakwater of modern construction which, in spite of weaknesses inherent in the original design, has been made suitable to the exposed situation in which it is placed. Originally designed as a rubble mound carried up to about the height of high water with concrete superstructure and parapet, the wastage of rubble on its sea face was found to be so serious that in the year 1913 it was decided to protect the rubble by the deposit of 40-ton concrete blocks placed "pell mell" over the whole of the seaward face of the mound above the level of L.W.O.S.T. Previous to this, the quantity of stone rubble deposited annually for maintenance purposes on the sea face averaged 85,000 tons for several years. The total length of the breakwater is half a mile.

The harbour breakwaters at Madras, in a position of extreme exposure, have suffered severe sea damage on many occasions, and large portions have been rebuilt and strengthened from time to time. The original harbour entrance on the east side between the ends of the two curved breakwaters was closed in 1910 on account of the serious "range" in the harbour, due to the position of the entrance and the rapid silting which was taking place. A new entrance was constructed on the north side of the harbour protected by a sheltering arm.<sup>1</sup> This arm, as well as the new portion of the breakwater closing the old entrance, is of sloping block work on a rubble foundation protected by 30-ton wave breaker blocks on the sea face. The outer portion of the sheltering arm was destroyed during a cyclone in Nov. 1916, and has since been reconstructed. The sloping or sliced block system of construction is to an increasing extent adopted both for breakwater and quay construction, particularly on foundations which are liable to settlement.

**Harbours.**—The bulk of new construction in connection with already existing harbours is in the direction of providing increased depth of water to meet the growing demands of shipping. In many cases of coastal harbours, existing breakwaters, moles or piers have been extended seaward, thus adding to the sheltered area water space of increased depth. In other cases entirely new breakwaters, or other means of shelter, have been constructed and in some already existing channels or sheltered areas have been deepened. Important harbour works, particularly in Africa, South America and the East, were undertaken in posi-

tions where no artificial protection previously existed, e.g., the African ports of Casa Blanca, Takoradi and Killindine and Antofagasta in Chili.

**The Mersey Bar.**—The formation and maintenance of a deep channel through the Mersey bar have been for many years problems of difficulty. Dredging by means of powerful sand pump dredgers is carried on almost continuously and the quantity of material removed in recent years from the bar channels and the river approaches averages about 20,000,000 tons annually. Since 1907 rubble stone training walls or revetments have been constructed on the east side of the Crosby channel and more recently the west side has been similarly treated, but in spite of these training works and intensive dredging the minimum depth of water in the Mersey approach channels has not been increased beyond the 26 ft. or 27 ft. at low water ordinary spring tide (L.W.O.S.T.) available in 1907.

#### DOCK CONSTRUCTION IN VARIOUS PORTS

In Great Britain, the principal developments in dock construction after 1910 took place in the Port of London, at Liverpool and at Southampton. Important works have also been carried out, or were (1926) in progress of construction, at Glasgow, Avonmouth, Immingham, Hull, Newport and elsewhere. On the continent of Europe perhaps the most important extensions have been made at Antwerp and Rotterdam, and the docks and basins of Havre, Marseilles, Dunkirk, Rouen and several Italian ports have also been extended. In the East large developments have taken place at Calcutta, Karachi and Bombay, as well as in many of the ports of Australasia and Japan.

**Port of London.**—Since the Port of London Authority was constituted in 1909 to take over the docks of the previously existing dock companies and the tidal portion of the Thames Conservancy jurisdiction, £12,000,000 had been spent up to 1926 on improvements in the port. The King George V. Dock, an extension of the Royal Albert Dock, is the most important addition. Commenced in 1912, it was opened for traffic in July 1921. The wet dock has an area of about 64 ac., a depth of water of 38 ft., and a total length of quayside of just over two miles. It is connected with the Royal Albert Dock by a passage 100 ft. wide. An entrance lock, 800 ft. long by 100 ft. wide, with a depth of water over the sills of 45 ft. at Trinity high water, gives access from the River Thames. A dry dock entered from the wet dock is 750 ft. long and 100 ft. wide, with a depth of 35 ft. over the keel blocks. An interesting feature of the wet dock is the provision of seven reinforced concrete jetties arranged in a line parallel with the south quay at a distance of 32 ft. therefrom. Each jetty carries six three-ton cranes. River barges lie between the jetty and the quay wall, and the cranes upon the jetties can deal with goods on the quay or in the ship or barges. The quay walls of this dock are of concrete with vertical faces. The water level of the dock is maintained permanently at a level of 2 ft. 6 in. above Trinity high water by means of impounding pumps. This system of raising the dock water level has been adopted since 1910 in the case of most of the London docks with the object of increasing the available depth in the berths alongside the quay walls.

At Tilbury a new branch dock was constructed as an extension of the old Tilbury dock, adding approximately 17 ac. to its water area. A portion of the quay walls of this dock consists of built-up concrete well monoliths, sunk from a level a little below the original ground

<sup>1</sup> *Proc. Inst. C. E.*, vol. 190 (1911-2).

surface, with mass concrete superstructure, and affords a typical example of modern practice in quay construction in comparatively bad ground.<sup>1</sup>

A river cargo jetty of reinforced concrete sited alongside the deep water channel of the river at Tilbury in 30 ft. of water at L.W.O.S.T. (low water ordinary spring tide) was completed in 1921. This jetty, a novel feature in the Port of London, 1,000 ft. in length and 50 ft. wide, is connected with the shore by means of an approach viaduct carrying a railway which extends over the roof of the storage sheds, forming a double-decked superstructure. Electric cranes placed on the upper deck unload cargo from ships alongside either into railway wagons or into the transit shed underneath or into barges in the waterway behind.

Among other improvements carried out by the Authority are extensions at the Surrey docks and new quays at most of the docks; storage and transit sheds have been modernised and extended, mechanical equipment has been installed for handling such imports as grain and frozen meat, and the river channel has been deepened successively until in 1925 a minimum depth of 27 ft. at low water ordinary spring tide was available from the sea up to the King George V. Dock. Oil wharves, constructed by private enterprise, have been built in the lower reaches of the river for dealing with the import of oil in bulk. Private enterprise is also responsible for improved facilities in the port for handling seaborne coal imports.

**Liverpool.**—The Gladstone dock extensions were commenced by the Mersey Docks and Harbour Board at Liverpool in 1910. These new docks at the north or seaward end of the dock estate constitute the most important addition to the commercial docks of Great Britain made during the present century. The Gladstone dry dock, opened in 1913, was the largest in the kingdom, and at the time of its completion the largest in the world. It is 1,050 ft. long and 120 ft. wide at the entrance, which is closed by a sliding caisson. The depth over the sill is 44 ft. at H.W.O.S.T. (high water ordinary spring tide). Originally it was entered direct from the river, but was closed in 1922 during the building of the Gladstone wet docks, from whose water area the dry dock would ultimately be entered. The dry dock was constructed so as to be available for use as a berthing dock when not required for dry docking purposes, and its side walls are equipped as quays with cargo cranes and transit sheds. The new wet docks, having a total water area of over 60 ac. are entered from the Mersey through a lock 1,070 ft. long and 130 ft. wide, sited so that its centre line is at a small angle with the frontage line of the Liverpool docks. At high water ordinary spring tide there is a depth of 48 ft. 9 in. over the sill, and at low water ordinary spring tide 21 ft. 8 in. The lock is closed by steel gates and is provided with an intermediate pair of gates subdividing it into two sections. The new docks contain 2½ m. of quays, to have at maximum high water a depth alongside of 54 feet. Treble storey transit sheds with flat roofs are provided on all quays and are equipped with electric cranes both on the quay frontage and on the roofs of the buildings. A new lock 90 ft. wide connects the Gladstone system of docks with the adjoining Hornby dock. It was expected that the new docks would be completed about the end of the year 1926. Concurrently with these extensions several of the older docks at Liverpool have been improved or enlarged since 1910, and a new 80 ft. entrance lock has been made at the Alfred dock, Birkenhead.

**Southampton.**—The port of Southampton was for many years one of the two principal ports of Great Britain accommodating the largest class of transatlantic liners, and after the World War the largest of these vessels used Southampton in preference to Liverpool. As an indication of the provision which port authorities regard as necessary for traffic of this description, the scheme of dock extensions approved by the Southern Railway Co. in 1924 may be briefly mentioned. Preliminary work on this scheme was put in progress. All the ship berths at Southampton are tidal, and there are no closed wet docks at the port. The extensions were to be constructed on the north side of the river Test, to cover a frontage of about two miles. Deep water jetties, each 1,000 ft. in length, mainly of reinforced concrete with a depth of 35 ft. at low water alongside, to be increased by dredging to 45 ft., were to be constructed, graving docks larger than any existing to be built, and a square mile of foreshore reclaimed from the sea. The cost of the work was estimated to be about £13,000,000.

Since 1910 the Trafalgar dry dock at Southampton has been enlarged, and is 912 ft. long internally, 100 ft. wide at the entrance, closed by a sliding caisson, and has 35 ft. of water over the sill at high water. The Ocean dock, opened in 1912, is an open basin of 16 ac., having a depth of water alongside the quays of 40 ft. at low water ordinary spring tide, the walls being designed for a depth of 45 ft., which can be attained by further dredging. The berths in the Ocean dock accommodate the largest transatlantic liners, such as the "Majestic." The approaches to Southampton are dredged to give a minimum depth in the navigable channel of 35 ft. at low water.

**Dublin Quay Wall.**—A quay wall constructed in the Port of Dublin, 1923-4, is an example of a form of monolith construction which differs from that described above in the case of the Tilbury dock walls. Reinforced concrete cellular caisson monoliths 40 ft. long, 41 ft. high and 28 ft. wide were floated into position and

sunk in a trench previously dredged to and prepared at the correct level for the foundations. The cells of the monoliths, each of which weighed about 1,200 tons, were afterwards filled in with concrete and gravel and surmounted by a mass concrete superstructure wall (fig. 2). The berth in front of the quay, 35 ft. deep at low water, was subsequently dredged to the required depth.

**Antwerp.**—The enlargement and modernising of the port of Antwerp on a large scale was undertaken in 1913, but at the commencement of the World War a small part only of the new works had been constructed. Operations were resumed in 1921. A *bassin canal*, which is in effect a series of enclosed docks, extending from Kruijschans, on the Scheldt seven miles below the city to the old dock system higher up the river at Antwerp was put in course of construction. The lock at Kruijschans is 886 ft. long, 115 ft. wide and has a depth over the sill of 46 ft. at high water. For the construction of these works caisson and concrete monolith foundations have been extensively employed.

**India.**—The construction of the King George Docks at Calcutta, commenced in 1920, when completed in 1927, were to provide ample accommodation for the trade of that port for years to come. One hundred and ninety ac. of water surface and 25,000 lineal ft. of deep water quay frontage would be available in the new wet docks. Here again well monoliths of large dimensions, sunk through the alluvial material of the Ganges delta, were employed for the construction of the quay walls and other works. At Bombay, a wet dock of 50 ac., commenced in 1905, was opened in 1914. The entrance lock, 750 ft. long and 100 ft. wide, has a depth over the entrance sill of 41 ft. 3 in. at high water ordinary spring tide. The Hughes dry dock at Bombay, constructed about the same time as the wet dock, is 1,000 ft. long with an entrance 100 ft. in width. At Karachi, additional accommodation on a large scale has been made by the construction of deep water tidal wharves, and a similar course has been adopted at Rangoon.

**South Africa.**—In South Africa, the port of Durban has been improved by the dredging of the bar, entrance channel and harbour, the normal depth available at low water being now 31 feet. Berths alongside the principal open tidal wharves have depths up to 38 ft. 6 in. at low water. At Cape Town the Victoria basin, 67 ac. in extent, provides sheltered berths alongside quays with 36 ft. to 40 ft. water at low water ordinary spring tide, and the breakwater is now (1926) extended.

At Port Elizabeth, breakwaters which will enclose a harbour of 87 ac. were in course of construction in 1926, the available depth in the harbour at low water being 36 feet. Both at Cape Town and Durban facilities for the shipment of grain on a large scale have been provided.

**Australia and New Zealand.**—In the principal ports of Australia where the tidal range is small, open wharves and jetties have been constructed to keep pace with the demands of shipping. At Sydney, Adelaide and Hobart, depths of 35 ft. or more are provided alongside the open quays or jetties. Berths having 37 ft. depth at low water are provided at Melbourne. In New Zealand, Auckland and Wellington provide for 35 ft. and 36 ft. depth respectively.

**North America.**—On the Atlantic and Pacific coasts of North America, where the tidal range is usually small and the majority of the larger ports are in situations possessing ample natural protection, e.g., New York and San Francisco, the necessary additional accommodation has been provided by the construction of long and wide jetties or wharves projecting from the shore into deep water alongside which vessels berth. Many of these jetties, or "docks" as they are termed in New York, have berths upwards of 1,000 ft. in length with 35 ft. to 45 ft. depth of water at low water. Timber and reinforced concrete piles are commonly employed for these structures, but sometimes reinforced concrete cylinders are used in place of piles for carrying the superstructure of the jetty. The Ballantyne Pier at Vancouver (fig. 3), completed in 1923, is a good example of recent construction. It is 1,200 ft. in length, 341 ft. wide, with a depth of water in the berths of 45 ft. at low water. The heart of the pier is formed of sand and gravel filling; the outer rows of columns carrying the reinforced concrete superstructure consist of 7 ft. diameter reinforced concrete cylinders, and the inner rows are carried on clusters of piles. Two-storey transit sheds, railways and cranes are carried upon the superstructure.<sup>2</sup>

#### NAVAL DOCKYARDS

The naval dockyard at Rosyth, on the north side of the Firth of Forth, was in course of construction when the World War broke out. The works had been commenced in 1909 and, although a large part of the accommodation was available for the fleet during the War, construction continued until 1921. The Rosyth dockyard occupies a site on the foreshore of the Firth above the Forth bridge, and comprises a closed basin of 54 ac., open wharves, an entrance lock 850 ft. long, 100 ft. wide at sill level, and having a depth of 54 ft. over the sill at high water. There are three dry docks having dimensions approximating to those of the lock and depths of 40 ft. over the sills. The lock itself can be used as a dry dock if necessary. In addition to the lock there is a tidal entrance to the basin 115 ft. wide at sill level. Concrete well monoliths were used extensively in constructing the basin and other walls. H. M. Govt. decided in 1925 to

<sup>1</sup> *Proc. Inst. C. E.*, vol. 215 (1922-3).

<sup>2</sup> *Inst. C. E. Selected Papers* No. 27 (1925).

FIG. 2.—Ballantyne Pier Vancouver.. Outer Berths.

reduce the dockyards at Rosyth and Pembroke to a care and maintenance basis, and to concentrate all Admiralty home dockyard work at the remaining yards at Portsmouth, Devonport, Chatham and Sheerness. To meet the growing needs of the navy, new locks and a dry dock were constructed at Portsmouth and completed shortly before the War, the dimensions of which are practically identical with those at Rosyth. The largest of the Devonport locks and dry docks are of somewhat smaller dimensions. In 1922 the Admiralty initiated a scheme for the construction of a great naval dockyard at Singapore. The preparatory work which was already in hand was cancelled by the Government early in 1924, but with the advent of a new Ministry work was resumed at the end of that year.

The navy departments of other nations, particularly the United States and Japan, have carried out the construction of new docks to meet the growing requirements of their fleets. The German naval dockyards at Wilhelmshaven, Kiel and Brunsbüttel, the construction or improvement of which had been actively carried on in the years immediately preceding the War, were partially dismantled conformably with the peace conditions, and the naval harbour works at Heligoland were demolished under the supervision of the Allies (1920-2).

#### DRY AND FLOATING DOCKS

**Dry Docks.**—In addition to the dry docks which are mentioned in the foregoing paragraphs, large dry docks were completed in the years immediately preceding or following the War in many parts of the world. At Esquimalt, Victoria, B.C., a dock completed in 1925 has an entrance 125 ft. in width with a depth of water of 40 ft. over the sill. This dock is 1,150 ft. in length. The Congella dry dock at Durban, opened by the Prince of Wales in 1925, is 110 ft. in width at entrance and 1,150 ft. long; the depth over the sill is 35 ft. at low water ordinary spring tide. At Havre a dry dock commenced in 1911 was nearing completion in 1926. A novel method was adopted for its construction on a foundation of sand and silt. The entire dock structure is built in and upon a huge steel caisson framework 1,132 ft. by 197 ft., which was floated into position over the site of the dock previously dredged to the required depth and there sunk in place. The dock is 1,023 ft. long internally, 125 ft. wide at the entrance, with a depth over the sill of 52 ft. 6 in. at high water ordinary spring tide. The Balboa dry dock at the Pacific end of the Panama Canal, opened in 1916, is 1,110 ft. long, 110 ft. wide, with 41 ft. 5 in. over the blocks at mean high water. Other large dry docks are the Boston U.S. Navy dock, 1,170 ft. by 114 ft., and that at St. John, New Brunswick, 1,165 ft. by 125 feet.

**Floating Docks.**—The largest floating dock in the world, that at Southampton, was opened by the Prince of Wales on June 27 1924. Designed to accommodate the largest ship afloat, it has an overall length of 960 ft., a clear width of 130 ft. 8 in. and a total lifting power of 60,000 tons. The dock can be submerged to take in ships drawing 38 ft., and the berth where it is moored is dredged to a depth of 61 ft. at low water ordinary spring tide. This dock is of the self-docking type, and is constructed in seven separate sections.

**Dock and Lock Entrances.**—For closing the entrances of large dry docks steel caissons are used in most modern instances either of the sliding type, as at Rosyth and Durban, or the floating pattern, of which examples are found at the Hughes dock, Bombay, Havre and the Calcutta dock. Sliding caissons, although more costly than floating caissons, have the advantage of being more easily and rapidly moved, and, moreover, they are more convenient for the provision of railway tracks and roadways over them. Steel gates are generally preferred for closing the entrances to large locks and wet docks, although sliding or ship caissons have been adopted in the case of Admiralty wet dock entrances, including Rosyth and Portsmouth, and at the King George docks, Calcutta. The majority of modern steel gates are of the semi-buoyant type provided with buoyancy chambers, which relieve the anchorage at the head of the heel post of a great part of the horizontal stress due to the weight of the gate. In such cases the use of rollers and roller paths under the mitre posts is commonly dispensed with.

A feature of the design of all modern dry docks, locks and wet docks is the construction of entrances rectangular in form, thus approximating to the box shape of the hulls of modern steamships. For operating sliding caissons both electric and hydraulic power have been employed. For gate opening, machinery of the largest type hydraulic power is preferred in Great Britain, but electric machinery is employed generally on the continent of Europe and in America, as, for instance, for the gates of the Panama Canal locks.

**PORTER, HORACE** (1837-1921), American diplomatist and soldier (see 22.116), died in New York City May 29 1921.

**PORTER, WILLIAM SYDNEY:** see HENRY, O.

**PORTLAND, Ore., U.S.A.** (see 22.120), the financial, industrial and distributing centre of the vast Columbia river basin, increased 24.6% in the decade after 1910, to a population of 258,288 in 1920, of whom 3,771 were Chinese, Japanese and Indians, 1,556 negroes and 49,778 foreign-born (white and coloured). The census bureau estimate for 1925 was 282,383; the local estimate for the metropolitan area 460,000. Annexations of territory increased the area to 63.2 square miles.

By the expenditure of \$16,000,000 by the Federal Govt., and \$4,500,000 by the city, the entrance to the harbour was improved, deepened and protected by two rock jetties, and the river channel was deepened to accommodate vessels of 30-ft. draft at zero stage, from the mouth of the river to Portland. By 1925, 54 steamship lines were giving regular service to the principal ports of the world. The harbour (fresh water, with a frontage of 29 m. within the city limits) had berthing space for 100 vessels, 65 ac. of cargo space, 6.5 m. of docks, 50 piers, 4 municipal terminals and many private docks, especially for lumber, grain and flour. During the first five years after the close of the World War, the foreign commerce of the port increased by 196% in tonnage, to 1,506,210 tons (1924); and local trade by 114% to 2,872,147 tons. Outbound shipments (by rail and water) consisted chiefly of lumber, apples, flour, wheat,

paper, prunes, barley, canned fruits, salmon (gradually decreasing), cascara, copper, hides and wool, doors, ready-made houses (largely to Japan), furniture and other articles of woodwork. Building permits in the five years following the War amounted to 77,545, representing a value of \$116,355,966. The output of the manufacturing establishments within the city limits was valued at \$46,861,000 in 1909; \$196,380,000 in 1919; and \$154,414,779 in 1923. The commission form of government was adopted in 1913; a permanent zoning commission was established in 1918; and a housing scheme was adopted in 1919. A system of main streets, park roads and boulevards was laid out and grade crossings were eliminated.

**PORTO RICO** (see 22.124).—Porto Rico has an area of 3,435 sq. m., and the census of 1922 gave the population as 1,346,623 or 32.14 per square mile. In consequence of this continued growth, education and health remain grave problems. The total enrolment in all schools supported by public funds was 227,267 in 1924; but the percentage of illiteracy in the island is large. The death rate for 1924 was 18.7 per 1,000 inhabitants as compared with 24.97 in 1911. But in 1920 tuberculosis, malaria and uncinariasis (hookworm), together with infant mortality, still accounted for 60% of the total death rate, and even in 1924, deaths among children under five years of age constituted 45.3% of the general mortality. Important preventive work has been carried on by the insular board of health, including an intensive campaign for the control of uncinariasis, in co-operation with the Rockefeller Foundation.

But the influence of basic economic and social conditions is still felt. "Our population is one of the densest on earth," the insular commissioner of health, himself a distinguished Porto Rican, wrote in 1920. "More than 70% are in the country, badly housed and fed, ill in health and ignorant of the first principles of hygiene. Until the people have learned to preserve and protect their health and have more ample means to provide themselves with better houses and food, so as to reduce their miseries, no positive result, no recompense for all our efforts can be obtained."

**Political History.**—Important developments in the affairs of Porto Rico—political, economic, social—took place in the period 1910–25. Politically, the organic law was first amended and later materially changed. Economically, the agriculture and commerce of the island showed notable increase. Social progress was shown in the improvement of living conditions, the spread of elementary education and the reduction of poverty and disease. The Foraker Act, approved by Congress April 12 1900, under which the island had been administered for the first decade of its existence under the American flag, was amended by the Olmsted Act, approved by Congress July 15 1909, which placed the supervision of Porto Rican affairs in the jurisdiction of an executive department to be designated by the President. The President subsequently designated the War Department. To prevent recurrent deadlocks over the insular budget, provision was made that if the Legislature failed to pass the Appropriation bill for an ensuing fiscal year, the sums authorised for the current year should be deemed to have been appropriated and might be lawfully expended.

**Constitutional Changes.**—Far more thorough-going were the changes affected by the passage of the Jones Act, approved by Congress March 2 1917, which provided that citizens of Porto Rico should be deemed and held to be citizens of the United States. Six executive departments were constituted: Justice, Finance, Interior, Education, Agriculture, Labour and Health. The governor, the attorney-general and the commissioner of education are appointed by the President of the United States, subject to the approval of the U.S. Senate; the heads of the remaining departments by the governor of Porto Rico, subject to the approval of the Porto Rican Senate. The law-making power is vested in a Legislature consisting of a Senate of 19 members and a House of Representatives of 39 members, all elected by manhood suffrage for a term of four years. Acts of the Legislature may be vetoed by the governor; but his veto may be overridden by a two-thirds vote. The President of the United States

may nevertheless interpose a final veto. Matters relating to franchises and concessions are vested in a public service commission consisting of the heads of the executive departments, the auditor and two elected commissioners. A resident commissioner to the United States, paid by the Federal Govt., is elected by popular vote for a term of four years; he represents the island in the U.S. House of Representatives, with a voice but without vote, and is recognised by all departments in Washington.

**Industry and Trade.**—The economic experience of the years 1910–25 was the increased and more profitable production of sugar, tobacco, coffee and fruits, consequent in the first instance upon duty-free access to the American market, and aided by the completion of irrigation projects. The increase of exports was accompanied by larger imports, by a reversal of the island's adverse trade balance, and by an appreciable, though unequal, diffusion of gain among the island's population, the growers of sugar and tobacco being specially benefited. The commerce of the island more than doubled in the period, the combined value of imports and exports rising from \$78,705,364 in 1911 to \$176,456,497 in 1924.

This amazing growth was uneven. The activity of 1911–2 was followed by reaction in 1913, accentuated by the dislocations consequent upon the outbreak of the World War. War demand for the island's principal articles of commerce made itself sharply felt in 1916–7 but slackened in 1918–9. In 1920 came remarkable developments, exports rising from \$79,496,040 in the preceding year to \$150,811,449 and imports from \$62,400,360 to \$96,388,534. The factor directly responsible was the world boom in sugar, and to a less degree in tobacco and coffee. Sugar exports in tonnage were actually less in 1920 than in 1916 and in 1917, the price per ton rising from \$75.81 in 1911 to \$136.77 in 1919 and to \$235.88 in 1920. The "bubble" burst in 1921; but the succeeding years brought notable recovery, so that in 1924 both imports (\$89,369,624) and exports (\$87,086,873) were much beyond those obtained during the World War period. The visible trade balance in favour of the island rose from a previous maximum of \$27,636,780 (1916) to \$54,422,915 in 1920, and later became more normal at \$10,627,820 (1923). The great bulk of this trade, 91% in 1924, was with the United States.

There was marked improvement during the period in the island's material equipment. New schools were erected and additional roads and bridges constructed. Even the remoter towns of the interior had in 1925 waterworks and electric lighting plants which had been made possible by loans from the Treasury. The increase in private wealth was reflected in the erection of many fine residences, while the development of commerce and agriculture stimulated the extension of banking and transport facilities.

**Finance.**—The basis of the insular revenue system remained that put into operation with the establishment of civil government under the American flag by the Hollander law, later modified and adapted to meet changing conditions. Ordinary expenditures for the fiscal year 1924 were \$12,431,724 as compared with \$3,685,613 in 1911. The total assessed valuation of all property for purposes of taxation in 1924 was \$312,384,305 as compared with \$133,817,931 in 1911.

The governors were George R. Colton, 1909–13; Arthur Yager, 1913–21; E. Mont Reilly, 1921–3; Horace M. Towner, 1923–.

**BIBLIOGRAPHY.**—S. Bonsall, *The American Mediterranean* (1912); A. Hyatt Verrill, *Porto Rico Past and Present* (1914); C. L. Jones, *Caribbean Interests of the United States* (1916). (J. H. Ho.)

**PORTSMOUTH**, England (see 22.132), with a population of 247,284 in 1921, and an area of 7,964 ac. (including 87 of water, 522 of tidal water and 1,377 of foreshore), was made a city in 1926. Cosham was included in the borough in 1920. The parliamentary borough was divided into central, north and south divisions in 1918, each returning one member to Parliament.

In 1924 the foundation of a new diocese of Portsmouth and the Isle of Wight, taken from that of Winchester, was approved; a commission of inquiry recommended that the old parish church of Portsmouth, St. Thomas', should be the pro-cathedral. New

churches include St. Alban's, Copnor Road; St. Saviour's, Landport (1914); St. John's (Winchester College Mission) and St. Cuthbert's, Copnor (1916); and a Roman Catholic church at Copnor (1911). The large church of St. Matthew, which had been in process of erection for 22 years, was finished in 1924. A church has been built and a parish and cemetery made at Milton. The Portsmouth war memorial has taken the form of new wards, an administrative block and a gateway, at the Royal Portsmouth hospital, and a cenotaph in the Town Hall Square. Large sums have been spent by the municipality on drainage schemes and esplanades, and Southsea Common has been taken over from the War Office and laid out as a public pleasure-ground. The fine castle of Porchester, with remains from Roman down to medieval times, came into the custody of H.M. Office of Works, as an "ancient monument," in 1926. Portsmouth, besides being an important naval establishment and arsenal, has a considerable coastal trade, and a new industry, the refitting of liners, has been started. The historic "Victory" was in dock for repairs in 1925.

**PORT TALBOT**, GLAMORGANSHIRE, with a population (1921) of 40,039 and an area of 25,645 acres, was formed into a borough by the amalgamation in 1921 of the parishes of Aberavon, Margam, Michaelston Lower, Cwmavon Lower and part of Baglan Lower. The borough, with three outlying parishes, forms the Aberavon parliamentary division, returning one member. New municipal buildings and a public library were opened in 1915, and a general hospital in 1916. The church of St. Agnes was built in 1910, and that of St. John in 1912. In 1925 Lord Jersey gave 12 acres of land to be made into a seaside park, in order to provide work for the unemployed. The harbour has an area of about 250 ac., with 90 ac. of dock-space.

**PORTUGAL** (see 22.134) has been a Republic since Oct. 1910. Its area, including the Azores and Madeira, is 35,490 sq. miles, and the population, 6,399,355 (1920 census).

### I. POLITICAL HISTORY

The political history of Portugal from the revolution of 1910, when the monarchy was overthrown, is a record of short-lived ministries and of revolutionary outbreaks during which the only stable periods where those associated with the control exercised by President Paes, assassinated in Dec. 1918, and with the Ministry of Senhor da Silva, which lasted for 21 months. Royalist invasions, the activities of the Carbonarios, mutinies, strikes and outrages in Lisbon and other towns, rendered the authority of successive administrations precarious in the extreme, and their difficulties were increased by the conflicts between Church and State, the rise in prices, and the general unrest created by the War.

The effects of the revolution fell most heavily on the poor of the country districts and, in consequence, emigration increased to an unprecedented extent, rising from 6.83 per 1,000 in 1910 to 14.85 per 1,000 in 1912. In the towns, discontent with the working of the republic was prevalent; lavish promises had aroused impossible hopes among the people, and by many the republic was regarded as but a first step towards a more Radical workmen's republic. Socialism and syndicalism developed rapidly. The right to strike at 24 hours' notice, conceded on Dec. 7 1910, was followed by strikes of all kinds, including several serious railway strikes. The disorders culminated in the demonstration against Parliament on Aug. 2 1911, and the general strike at Lisbon on Jan. 31 1912, when the city was placed under martial law and over 1,000 workmen suspected of syndicalism were arrested.

The Provisional Govt. of the republic consisted of Dr. Theophilo Braga (1843-1924), president, Dr. Antonio José de Almeida (Home Affairs), Dr. Alfonso Costa (Justice), Col. Corrêa Barreto (War), Dr. Amaro Azevedo Gomes (Marine), Dr. Bernardino Machado (Foreign Affairs), Dr. Basilio Telles and, later, Dr. José Relvas (Finance). Dr. Antonio Luiz Gomes and, later, Dr. Brito Camacho (Public Works). It lasted till Aug. 24 1911.

*The Constitution.*—On March 18 1911, the new electoral law came into force. It gave the vote to all Portuguese over 21

years of age who could read or write, including priests and officers of the army or navy, but excluding naturalised Portuguese, officers on the active list and persons proscribed politically. Lisbon and Oporto (voting on the proportional system) were to return 10 deputies each, the other districts four and the colonies one each. By a modification of Jan. 11 1915, Lisbon received 20 deputies, Oporto 10, the remaining constituencies between one and four each. By a decree of March 11 1918, universal suffrage for all citizens over 21 was established, but illiterates (75% of the population) were again disfranchised in 1919. By the law of 1918 the number of deputies was reduced to 155, returned by 51 constituencies, of which Lisbon returned 14, Oporto 6. The representation in the Senate, consisting of 77 members, was made regional and professional. By a decree of April 26 1918, soldiers and sailors on active service were allowed to vote. In the elections held on May 28 1911 many of the candidates were nominated by the authorities without opposition and, even where there was an election, the government candidates were returned without difficulty, no Royalists offering themselves.

The Constitutional Assembly was opened on June 19 1911, and a decree was passed declaring the monarchy abolished and the House of Braganza forever banished. On Aug. 20 the new constitution was voted. It provided for two Chambers, that of the Deputies, consisting of 163 members to be elected every three years, and the Senate, consisting of 71 members. The president of the republic was to be elected by both chambers for four years and could not be re-elected. His salary was fixed at £3,600, with £1,200 for expenses. On Feb. 19 1920, he was given the right to dissolve Parliament, after consulting a special council appointed for this purpose.

The first president under the new constitution was Dr. Manuel de Arriaga (born in 1840, at Horta, in the Azores), who, on Aug. 24 defeated the Radical candidate, Dr. Bernardino Machado, the Conservative candidate, Senhor Braamcamp Freire, having withdrawn. Dr. João Chagas (d. 1925) was Premier and Minister of Home Affairs in the first Constitutional Ministry. One of the first measures was to vote the payment to each deputy of 17s. for each sitting of the assembly. Congress in Feb. 1926, approved a proposal for the revision of the constitution.

*Church and State.*—The anti-clerical policy of the Provisional Govt. had entailed serious difficulties. The bishops signed a pastoral letter of protest and on March 8 1911, the Bishop of Oporto was removed from his see. The religious orders had been expelled by the decree of Oct. 8 1910, their property confiscated and the convents closed. By that of Oct. 22 the teaching of religion in the primary schools was forbidden. Marriage of priests became legal. The decree of separation between Church and State was drawn up, under the date of April 20 1911, by Dr. Alfonso Costa, then Minister of Justice. The Roman Catholic religion ceased to be that of the State, which recognised all creeds as of equal authority.

This decree contributed towards alienating the north of Portugal from the republic. The Patriarch of Lisbon and the Bishop of Guarda published a pastoral letter forbidding the clergy to accept salaries from the state. For consistent opposition to the law of separation the Bishop of Guarda and the Patriarch of Lisbon were banished from their dioceses for two years.

After the promulgation of the law of separation, the Portuguese Legation at the Vatican was suppressed July 10 1913. The law was extended in Nov. 1913 to the Portuguese colonies, where the discouragement of Portuguese missions later gave rise to serious fears of the denationalisation of the colonies<sup>1</sup> through the activity of foreign missionaries. When Paes subsequently became president, one of his first acts was to redress some of the grievances suffered under the law of separation, and, by a decree of Dec. 22 1917, banishment imposed on the priests was annulled,

<sup>1</sup> Administrative and financial autonomy was given to the Colonies on Aug. 15 1914. Decrees regulating native labour in Portuguese colonies in amplification of a fundamental law of May 27 1911 were promulgated on Oct. 1 1913 and Oct. 14 1914.

and the Cardinal Patriarch returned to Lisbon. Relations with the Vatican were resumed in 1918, and were maintained after President Paes's death.

*The Royalist Invasions.*—The main event of Senhor Chagas's premiership was the first Royalist invasion, commanded by Capt. Paiva Couceiro. Small Royalist risings had been suppressed during the summer of 1911, but Capt. Couceiro still threatened the northern frontier. Successful representations were made by the Republic to the Spanish Govt., which was itself suffering from the action of Portuguese Republicans in Spain, and steamers were detained and war material seized. Couceiro crossed the frontier on Oct. 3 at the head of about 1,000 men, not a quarter of whom were armed with rifles. He advanced in the direction of Braganza, and took the small town of Vinhaes, but evacuated it on Oct. 6 and, after maintaining himself for a fortnight in the hills, recrossed the frontier. A Royalist rising in Oporto, timed to coincide with this invasion, was brought prematurely to a head by Carbonario agents on Sept. 29.

King Manoel and the pretender Dom Miguel met at Dover on Feb. 6 1912. On July 7 Couceiro again crossed the frontier, with a slightly larger force, but most of his arms and ammunition had been seized in Belgium and Galicia. The Royalists' attacks on Valença and Chaves failed, and within a week they returned to Spain. Royalist risings in the northern provinces were speedily suppressed, and great excitement prevailed in the south, where the Carbonarios discovered a Royalist plot at Torres Vedras. Dr. José de Almeida and other prisoners of war were tried by a court-martial and confined in the Lisbon Penitenciaría.

*The Political Trials.*—The arrests after the invasions of 1911 and 1912 were very numerous. Special tribunals were set up in Lisbon and Oporto in Jan. 1911, to try cases of political conspiracy, and in July 1912, Parliament voted still more stringent laws of defence. Thousands of persons were summarily arrested without the formulation of any definite charge and were confined for months in subterranean dungeons. The chief instrument of this widespread system of espionage was the organisation of the Carbonarios. This secret society, the *Jov. Port.* (Young Portugal), founded or revived by Arthur Duarte da Luze Almeida, forced through the Revolution of 1910 before the politicians were prepared for it. It assumed the functions of an unofficial police force, and at times proved itself strong enough to attack the Republican Govt. and the army. Its members, who carried arms, were Republicans of the most extreme type, and arrogated to themselves the right of summary arrest. Chagas estimated that on Oct. 23 1911 there were 2,000 political prisoners awaiting trial, of whom 700 were innocent.

Reforms were opposed by the Carbonarios and the Radical Republicans, and some of the worst outrages were committed under the weak Government which succeeded that of Chagas in Nov. 1911, with Dr. Augusto de Vasconcellos as Premier, and under the third Coalition Ministry formed by Dr. Duarte Leite in July 1912. Dr. Afonso Costa, the Radical leader, came into power in Jan. 1913, and under the pressure of public opinion, the Minister of Justice introduced a bill modifying the Penitenciaría régime, but the general amnesty was delayed till Feb. 1914. The situation had become one of growing unrest, and strikes were frequent. In April 1913, an attempted ultra-Radical *coup d'état*, in which a portion of the army and navy were implicated, was quelled, and in June the Government decreed the suppression of the Lisbon Syndicalist Club. In July a movement similar to that of April was marked at Lisbon by attacks on the military barracks, and was followed by numerous arrests. Dr. Afonso Costa, who gave much of his attention to finance, resigned on Feb. 9 1914, and Dr. Bernardino Machado became Premier. He was in office when Portugal definitely ranged herself on the side of the Allies during the World War.

*The World War.*—At a special joint sitting of both Chambers on Aug. 7 1914, Portugal proclaimed her loyalty to the British Alliance, and on Nov. 23 formally committed herself to participation in military operations. She served the cause of the Allies by furnishing munitions, guns and a division of artillery, and

acted in close co-operation with Great Britain. On Sept. 11 the first expedition of Portuguese troops left for Africa under the command of Col. Alves Roçadas and Massano de Amorim, and fresh contingents followed at intervals, 40,000 troops in all being dispatched for the defence of the colonies. Germany had not waited to be at war with Portugal in order to attack them.

As early as Aug. 24 1914, a raid was made on the Portuguese post of Maziwa on the northern frontier of Mozambique. On Oct. 19 the Germans attacked Naulila (on the Angola frontier), where more serious fighting occurred two months later, and on Oct. 30 they stormed the fortress of Kwangar and put the garrison to the sword. On April 11 1916, Portuguese troops occupied Kionga (south of the Rovuma river), which Germany had seized in 1894, and on May 27 they crossed the Rovuma river. They were still co-operating with the British in rounding up the Germans when the War ended. The British Govt. had deprecated any unnecessary intervention of Portugal in the War but agreed to the requisitioning of German ships lying in Portuguese ports, and this was carried into effect in Feb. 1916.

Consequently, Germany retaliated by declaring war on Portugal on March 9 and the declaration of war between Portugal and Austria followed on March 16. German submarines were active off the coast of Portugal during the autumn, many ships being sunk in 1917. By a decree of Jan. 17 1917, Gen. Fernando Tamagnini de Abreu (d. 1924) was given command of the Portuguese Expeditionary Force, and by July there were over 40,000 Portuguese troops on the Western Front, with 20,000 in Portugal ready to reinforce them. On April 9 1918, on the Lys river, the Portuguese contingent were subjected to a formidable attack by the Germans, and subsequently Portuguese troops took part in the entry into Lille.

*Political Movements During the War.*—On Dec. 13 1914, Dr. Machado was succeeded in the premiership by the democrat, Senhor Victor Hugo de Azevedo Coutinho, president of the Chamber of Deputies, with a view to holding the elections fixed for March 7, but the government's purpose was prevented by a military movement, and President Arriaga appealed to Gen. Pimenta de Castro to constitute a government representative of a wider body of opinion in the country; he formed a ministry on Jan. 28 1915. The action of the new Government was conciliatory and had the support of the moderate Republicans led by Dr. Antonio José de Almeida; foreign policy remained unchanged, but the activity of the Carbonarios was checked, the so-called Committee of Public Safety abolished and the refractory municipal councils dissolved.

The general election was now fixed for June 6 1915. In April an amnesty emptied the prisons. The democrats were, however, able to count on the support of the marines, and on May 14 the sailors mutinied, shot the captains of the "Almirante Reis" and "Vasco da Gama" and bombarded Lisbon, about 100 persons being killed. Pimenta de Castro resigned on May 15 and was arrested next day and transported to the Azores. The revolutionary committee nominated Chagas as Premier, but on May 16 he was shot at and wounded in the train on his way to Lisbon. Chagas died a few days later, and was succeeded by Dr. José de Castro. In a message addressed to Parliament Arriaga resigned the presidency as from May 29 (he died on March 5 1917); and after a short interim presidency under Dr. Theophilo Braga, he was definitely succeeded as president on Aug. 6 1915, by Dr. Bernardino Machado. The Government resigned in June, Castro again becoming premier, but he resigned in Nov. and Dr. Costa returned to office. On Dec. 5 1917, a revolution, directed against the internal policy of Costa and the Democrats, broke out at Lisbon. The rebels entrenched themselves in the Parque Eduardo VII., and their artillery opened fire upon the fleet. After two days' fighting, Gen. Norton de Mattos and Capt. Leotte do Rego took refuge on board a British ship in the Tagus. Dr. Costa and Dr. Soares were arrested; President Machado was placed under arrest, and on the 15th was banished. Vice-Adml. Machado dos Santos was released from prison, and with Maj. Sidonio Paes, the leader of the movement, and Capt. Feliciano Costa, formed

a revolutionary committee. A provisional government was now constituted, Maj. Paes becoming president and Minister for War and Foreign Affairs. The Radical sailors mutinied on Jan. 8 1918, and bombarded Lisbon, but the movement was easily quelled, and several hundreds were deported to Africa.

In March 1918, Paes reconstructed his Ministry, and the elections, on an enlarged franchise, were held on April 28. On the same day Paes was elected president, and was proclaimed president on May 9, the Powers recognising the new régime. Under a new system established in Oct. the president became also premier and ministers were called secretaries of state.

The first anniversary of the revolution was celebrated with national rejoicings on Dec. 5-8 1918, but on Dec. 14 President Paes was shot at the Rocio station by José Julio da Costa and died a few minutes later. On Dec. 16 Adml. João de Canto e Castro was provisionally elected president, and in Jan. 1919, Senhor Tamagnini Barbosa formed a Ministry, reviving the office of Premier. The Radical and Carbonario elements, which had hoped to benefit by the murder of President Paes, rapidly became impatient, and a democrat rising now broke out at Santarem, but the town was besieged by government troops and the rebels surrendered. The Royalists, too, were active, but the main result of their ill-timed risings was to fill the prisons and bring the Radicals into power. Dr. Egas Moniz (later replaced by Dr. Afonso Costa) was appointed to represent Portugal at the Peace Conference, and in Jan. 1919, at the instance of Great Britain, the number of delegates to the conference was increased to two. Portugal came out of the War with a crushing debt, but her colonies were assured to her and her economic future was promising. The Peace Treaty was ratified on March 30 1920. At the Spa Conference in July 1920, Portugal secured 0.75% as her share of the indemnity from Germany, and also received Kionga.

On June 1, Adml. Canto e Castro announced his intention of resigning the presidency, the democratic candidate, Dr. Antonio José de Almeida, being elected president on Aug. 6. There followed a succession of short-lived ministries and on March 2 1921, a new coalition Ministry, composed of off-shoots of the original republican democrat party, was formed, under the premiership of Dr. Bernardino Machado. A military pronunciamiento on May 20 caused the resignation of Dr. Machado. He was succeeded by a Liberal Ministry under Dr. Barros Queiroz, who dissolved Parliament and held a general election on July 10. Dr. Barros Queiroz was succeeded in the premiership by Dr. Antonio Granjo.

A solemn pledge had been taken to punish all who had supported the moderate republican, President Paes; in Oct. 1921, the barbarities culminated in the murder in cold blood of the Premier, Dr. Granjo, the founder of the Republic, Adml. Machado Santos, and other prominent persons. The appearance of foreign battleships in the Tagus made an impression, and brought the assassins to their senses for a time. Capt. Cunha Leal formed a short-lived Ministry and was succeeded in Feb. 1922, by Sr. Antonio Maria da Silva, who, despite many difficulties and several revolutionary movements, remained in office for 21 months. A number of Ministries, lasting two or three weeks apiece, followed his resignation, political instability being further increased by divisions in the Democrat party.

In the general election of Jan. 1922, the most striking feature was the Lisbon poll, the monarchist candidate, Sr. Carvalho da Silva, obtaining 3,903 votes, only 470 less than the successful democrat candidate, Dr. Afonso Costa. Each succeeding year saw one or more revolutionary movements, which had become a regular political weapon and were attended by little loss of life. Those of April and July 1925, were of a more conservative character and showed an inclination on the part of the army to expel the politicians from power. In Aug. 1923, Sr. Teixeira Gomes, Portuguese Minister in London, had been elected president of the republic in succession to Dr. Almeida, the first president to serve his full term of four years.

The absence of a firm guiding hand had been especially felt after the murder of President Paes, and successive governments

seemed to lose control over the finances. No government was strong enough to raise an internal loan, to revise the system of taxation, or levy a war-profits tax, and, while the taxes were paid in worthless paper money, the Govt. had to buy wheat and pay the service on the debt in gold. Social unrest was chronic; in March 1920, there was a general strike of civil and post and telegraph servants; a railway strike which began on Oct. 1 1920, lasted 70 days; and a newspaper strike in 1921 for over two months. The royalists showed themselves willing to exchange revolutionary for constitutional opposition, and King Manoel had constantly deprecated any revolutionary movement. The death of his uncle, the Duke of Oporto, in 1920, left King Manoel without an heir to the throne. Don Miguel, Duke of Viseu, and his father Don Miguel, Duke of Braganza, renounced their right to the throne of Portugal in favour of Don Duarte Nuno, the younger son of the latter, who was born Sept. 23 1907.

(A. F. G. B.)

The elections of Nov. 8 1925 gave a clear majority to the Democrats, who numbered 82 against 66 for all other parties, and it seemed at last that Portugal might achieve a comparatively stable government. The resignation of the President had long been expected, and when it took effect (Dec. 10) the election of his successor, Dr. Machado, took place without incident. The new Democrat Ministry formed on Dec. 16 consisted of experienced politicians, with Sr. Antonio da Silva once more as Premier. But on Feb. 2 1926 a military revolt broke out in Lisbon. It was rapidly quelled and the leaders deported. On May 30 a more serious revolutionary attempt was made. The new movement was in fact a continuation of the two abortive revolts of April 18 and July 19 of 1925, and Commander Mendes Cabecadas, leader of the July revolt, was one of the leaders. The other, General Gomez da Costa, had also been implicated in former risings. The outbreak of May 30 was a revolution led by the Army and provoked by the corruption and inefficiency of successive governments. On June 1 the whole country was in the hands of the revolutionaries, the President resigned, and Com. Cabecadas formed a provisional government with Gen. Gomez da Costa as Minister of War. The May revolution was the 18th *pronunciamento* since the foundation of the Republic and Sr. da Silva's Cabinet was the 40th to be overthrown in the same brief period.

(Ed. E.B.)

**Education.**—By the decree of March 29 1911, primary education became neutral, laic and compulsory. Each parish was to have at least one boys' and one girls' school, the cost to be shared between the state and the town councils. In the two following years 991 new schools were decreed, but in March 1913, 556 were still non-existent. The sum of £40,000, destined in 1913 for the building of primary schools, was apportioned among 180 schools. By a decree of Sept. 11 1913, in order to encourage industrial education and relieve the lyceums of Lisbon, Oporto and Coimbra, the number of students admissible to these latter was limited to a total of 4,850. Secondary education was remodelled by decrees of July 14 and Sept. 8 1918. In May 1914, a military school of aeronautics was created.

**Defence.**—On Jan. 19 1911, a commission appointed to reorganise the navy recommended the acquisition from Great Britain of three battleships of the dreadnought type, similar to the "Minas Geraes" of the Brazilian Navy. This recommendation was adopted in the new naval programme submitted by the Minister of Marine in Dec. 1911, which involved the purchase of three battleships of 20,000 tons each, three scouts of 3,000 tons, 12 torpedo-boats of 820 tons, and six submarines. On May 1 1912, a bill was introduced fixing the naval force at 4,500 men, as compared with 5,687 in 1910. On Jan. 27 1913, a commission was appointed for the creation of a naval arsenal on the south bank of the Tagus.

## II. ECONOMIC HISTORY

**Population.**—The population of continental Portugal, which includes the Azores and Madeira, amounted, in 1920, to 6,399,355 compared with a population of 5,957,985 in 1911. The colonies, which cover a total area of 804,841 sq. m., have a population of 9,675,000. Emigration has tended to keep the population fairly stationary. In 1919, emigrants mainly to the United States and Brazil numbered 31,138, while between 1912 and 1922 the total emigration was estimated at 700,000. According to the 1920 census, the population of the chief towns was as follows: Lisbon, 486,372; Oporto, 203,091; Setubal, 37,074; Braga, 21,970; Coimbra, 20,841; Evora, 16,148; Covilhã, 14,049; Faro, 12,925; Tavira, 11,043; Portalegre, 11,171; Elvas, 11,747; Aveiro, 10,357.

**Agriculture.**—Portugal is primarily an agricultural country, 60% of the population being engaged in agricultural pursuits. The land is exceedingly fertile owing to its sunny but moist climate; yet more than a third of the whole country still awaits exploitation and, indeed, between 1902 and 1921 there was an increase in the total amount of waste land from 43.1% to 49.1%. The principal handicap to agricultural development is the lack of adequate transport facilities. In many parts of the country, particularly in the south, the roads have deteriorated and the small sum of £8,000 sterling voted for their upkeep in the 1923 Budget is insufficient.

The state railways have also fallen into a serious state of disrepair, and, consequently, it has been found cheaper to import wheat direct from the Argentine than to send supplies to the north of Portugal from the Alemtejo. Lack of fertilisers is another serious handicap; it is estimated that 20,000 tons of additional fertilisers are necessary in the Alemtejo district alone, while other causes which check development are the excessive dependence on hand labour on the farms and, in the frontier districts, the tendency for labourers to cross into Spain, owing to the higher purchasing power of the peseta compared with the escudo. The most valuable crop is wheat, the average yield being six to seven quarters an acre and the harvest averaging 230,000 tons annually. The country, however, is compelled to import between 100,000 to 150,000 tons of wheat annually, despite the efforts of successive governments to encourage wheat growing, and the payment of these imports constitutes a heavy charge on the nation's finances.

Wine is the principal product of Portugal, accounting for 50% of its exports; the vineyards employ 100,000 hands. England alone imports over 6,000,000 gal., valued in 1923 at £2,080,170, despite the fact that the vintage in the port region of the Douro Valley in that year was a poor one. Table wines are produced all over the country, and are exported to Brazil and also to France. With the enforcement of prohibition in the United States, France, however, had no use for the Portuguese red wine which was used for mixing with the Bordeaux wine intended for American consumption, and the French efforts to prohibit the importation of Portuguese wines led to a war of reprisals between the two countries.

Portugal is the third olive producing country in the world, her olive trees occupying an acreage of 750,000 and giving 12,760,000 gals. of oil. Other crops grown on a large scale are maize, rye, oats and barley. About 200,000 tons of potatoes are produced, and there is a large export trade in fruit, mainly to England. Livestock is about equal in number to the population and an important industry is the production of corks which reaches about 70,000 tons annually.

**Commerce.**—Portuguese trade has been considerably hampered by the political uncertainty and by the fall and instability of the escudo whose value at par is 4s. 5½d. but which in 1925 was worth about 2½d. The War gave an impetus to the development of home manufactures, more particularly textiles, and, if the hopes of obtaining cheap power are realised, that impetus ought to continue. Great Britain is still Portugal's best customer, buying the greater portion of her port and madeira, her fruit, cork, sardines and mineral ore. After wine, the most important export is canned sardines and tunny fish, the principal customers being Great Britain and the United States. The annual value of these exports amounts to about £1,000,000 annually. Other exports are cork, pitprops, textiles (for Angola) and copper.

Portugal is hampered by the necessity of having to buy abroad foodstuffs, particularly wheat and maize and fish (bought from Newfoundland and Norway). The value of the oil imported now exceeds that of coal which averaged before the War about 1,000,000 to 1,500,000 tons, almost entirely bought from Great Britain. Cotton and woollen goods are also largely imported from Great Britain, agricultural machinery comes mainly from the United States and Germany; and Belgium supplies most of the railway material. As a result of the fall of the escudo, there has been a decline in Anglo-

Portuguese trade, Portugal's exports to Great Britain falling from £9,747,000 in 1918 to £4,589,000 in 1922 and in the first nine months of 1923 to £2,890,415. The general fall in foreign trade would have been more noticeable, if it had not been for the large importations of raw materials from Portuguese colonies.

**Manufactures.**—As already stated, there has been a considerable increase in Portuguese industries since the War, and Dr. Perez Trancoso, a former Finance Minister, has estimated that whereas before 1914 the number of those engaged in Portuguese industries other than agriculture was 60,000 or 1% of the population, 10 years later the number had increased to 500,000 or nearly 10% of the population. The principal manufacturing industry is the production of textiles, employing 45,000 workpeople, half of whom are in the cotton factories of Oporto and district, the remainder being engaged in the wool, silk and linen industries. Other industries are the making of tiles and the embroideries of Madeira, the annual export of which to the United States alone amounts to £2,000,000 annually. Wages have been increased between 20 and 30 times above the pre-War rates, in many cases more rapidly than the cost of living. Most of the labour disputes occurred in overcrowded Lisbon, though there were also troubles in Oporto and Covilhã. Many of these disputes affected shipping. The German mercantile marine is now the second largest carrier of Portuguese overseas trade, and is gradually gaining on British shipping.

**Finance.**—Portuguese financial difficulties are due to causes which may be summarised as follows: (1) The political and economic uncertainty caused by a series of weak and short-lived governments and by a number of costly strikes; (2) the tendency for the wealthy Portuguese to send their capital abroad, these sums amounting, it is said, to some £75,000,000; (3) the hoarding habits of the peasantry; (4) the large purchases of foodstuffs and raw materials from abroad; (5) foreign liabilities like the debt to Great Britain which, however, is not yet funded; and (6) the increase in the number of civil servants and in their emoluments. The estimated deficit for the fiscal year 1924-5 was 333,023,845 escudos, and the accumulated deficits since the War up to that year had reached 1,000,000 contos (a conto is 1,000 escudos). Financial reforms carried included the raising of port dues and shipping taxes, making the postal and telegraph rates the highest in Europe, and doubling the consular fees payable on all imported merchandise. By a series of prohibitions it was found possible to raise the exchange to about 2½d. at which figure it is hoped it may remain. The Bank of Portugal was compelled to issue between Jan. and Nov. 1923, notes to the amount of 238,699 contos, which increased the circulation beyond the legal limits of 1,160,000 contos. That excess was subsequently legalised and the limit increased. The uncertainty and speculation prevailing are further increased by the large number of small banks which cannot confine themselves to legitimate banking business.

**PORTUGUESE LITERATURE** (see 22.155).—Constant political unrest has been prejudicial to letters in a small country without a numerous leisured class, and no distinguished literary figure arose during the years 1910-25, but even before 1910 a reaction had begun against revolutionary methods in politics and laxity, or agnosticism in religion, which may lead to a healthier national life. This movement showed itself in the later works of Eça de Queiroz who had founded the Naturalist school, in the return to the Church of the prose writer Ramalho Ortigão and of the great poet Guerra Junqueiro, whose book, *Poesias dispersas*, dates from 1921, and it is found not only in the writers of the Integralist school (a Portuguese counterpart to the *L'Action française*) but even among men of advanced opinions like the novelist Manuel Ribeiro; most of the leading poets and prose writers are once more declared Catholics and they have gone back to the people for inspiration, with happy results.

Nationalism and regionalism have taken the place of naturalism and symbolism, which were copied from France and never commended themselves to Portuguese feeling as a whole. The prevailing political and economic gloom has driven the *intelligentsia* to seek salvation in the spirit of the race, which is essentially Catholic, and has survived in the hearts of the country dwellers, who form the vast majority of the population. The inability of 60% of these to read, saved many of them from losing their ideals and character during the period when a Liberal, destructive and anti-religious atmosphere permeated newspapers and books.

Under the influence of the movement referred to, and perhaps also of the 16th century, the golden age of letters, Eugénio de Castro, the doyen of living poets and once a rather artificial

Symbolist, developed a simple and natural manner in *Canções desta negra vida* (1922) containing the poignant *Song of a Poor Man's Lamp* and the witty *Song of an Old English Clock*, and in *Cravos de papel* (1922), gentle satire runs through short descriptive poems, clearly cut and almost popular in form. His later publications include *A Mantilha de Medronhos* (1923), impressions of Spain, *A Caixa de cem conchas* (1923), quatrains on the most varied subjects, slightly malicious but true to life, and *Chamas de uma candeia velha* (1925). The titles are happily chosen and suggest the spirit of the contents.

*Poets and Poetry.*—The most admired of the younger poets of this period, Antonio Correia de Oliveira, continued to draw inspiration from the soil and religion, as in the *Auto das Quatro Estações* (1911) and *Pão nosso, Vinho alegre, Azeite de Candeia* (1922), but his works are marred by repetition and an incapacity for sustained thought. The last defect is avoided in *A Minha terra* (1916) and in *A Criação*, a series of poems in various metres on the genesis of things; some true poetry mingles with much vague rhetoric and the versification shows technical skill. Augusto Gil, a hardly less esteemed poet, published three books, *Sombra de Juno* (1915), *Alba Plena* (1916) hymns of tender devotion on the life of the Blessed Virgin, and *A fralda de Cana* and he had the honour of a volume to himself in the *Anthology* of Agostinho de Campos. Teixeira de Pascoas, a sincere but nebulous pantheist, the inventor of what is called *saudosismo*, wrote a tragedy in verse on the late King Carlos, devoid of dramatic situations but remarkable for its beautiful lyrics. Not only Portuguese but Spanish critics have hailed him as a great poet and some of his compositions have been compared to those of Wordsworth. Love of nature distinguishes him, but he pays too little attention to form, though his verse has a music of its own. Affonso Lopes Vieira, a writer of exquisite taste and sense of rhythm, translated the traditions of the race and the poetry of the sea in *Ilhas de Bruma* (1918) and produced *refacimentos* of two works of world fame in his *Amadis* and *Diana*, marked by rare artistry and understanding of the originals. The last publication of the Republican politician João de Barros, prolific in verse and prose, is a poem *Sísifo*, in which he treats the classical legend in a novel way.

*Prose Writers.*—The new manner is seen even more clearly in prose and especially in the novel, though it did not touch the austere Republican and conscientious analyst of middle-class society Teixeira de Queiroz (d. 1919). Following in the steps of Oliveira Martins, Anthero de Figueiredo has sought to combine history and art in *D. Pedro e D. Ines* (1913) and *Leonor Telles* (1916) and above all in *D. Sebastião* (1924), where he revives the figure of the last crusading king, and by the aid of contemporary accounts paints a picture of the times with abundant imagination. It is a frankly nationalistic book, but though the author at the close exhorts his countrymen to educate themselves and work, it is to be feared that his panegyric of the noble but headstrong monarch may have a contrary effect to the one intended. His *Espanha* (1923), *Jornadas em Portugal* (1918) and *Senhora do Amparo* (1920) are regional works, in a glowing style, which in the second suffers from over elaboration.

The lack of a sound classical education is too evident in modern Portuguese prose, and few dare to attempt the straightforward narrative, sparing of adjectives and uncommon words, which is the chief attraction of the classics. Raul Brandão is an exception: his *Pescadores* (1924), dedicated to "my grandfather who died at sea," tells of fisher folk and the tragedy of the ocean with poignant realism, and contains magnificent descriptions of the coast scenery from north to south, ending at Sagres, the town of Prince Henry the Navigator. The book is worthy of the author of *Os Pobres* (1921). The trilogy of Manoel Ribeiro, *A Cathedral*, probably suggested by Huysmans, *O Deserto* and *A Ressurreição*, constitute a remarkable performance in subject and atmosphere, without precedent in modern Portuguese, and its popularity is not less remarkable. No better proof could be adduced of the changed times than these "clerical" books by a man of far from clerical ideas. At the close of this period he initiated a new trilogy with *A Colina Sagrada* (1926). The nat-

uralism of Eça de Queiroz found a fresh interpreter in Aquilino Ribeiro, a novelist highly considered throughout the Peninsula, whose works sold by the thousand. Equal as a psychologist to his master and possessed of a rich vocabulary, no one can create characters or picture one side of country life so faithfully as he has done in *A Via Sinuosa* (1918). In 1925 he produced *Filhas de Babilônia*, an unpleasant book, and *Estrada de Santiago*. The voluminous João Grave added *Gente Pobre* (1912), *Parsifal* and *A vida e Paixão da Infância* to his list of romances. Sousa Costa the novel *Romeu e Julieta*, and a brilliant satire on contemporary political events is to be found in *Saude e Fraternidade* by Campos Monteiro. The *Genie de Palmo e Meio* of Augusto all contain delightful short stories.

*The Drama.*—The drama is, as ever in Portugal, the weak spot and there are few original plays of merit to record; the theatre continuing to live for the most part on versions from the French. Julio Dantas added to his repertory *O Reposteiro Verde* (1912), a successful piece, and *Mariana*, but they only confirmed and did not increase his reputation. Among other pieces may be mentioned *O herdeiro* and *Entre Giestas* of Carlos Selvagem, a talented prose writer, *D. João e a mascara* (1924) and the lyrical play *Diniz e Isabel* (1919) of Antonio Patricio, *O Gebo e a Sombra* (1923), a tragedy of unrelieved gloom and considerable power by Raul Brandão, and *Egas Moniz* (1918) by Dr. Jaime Cortesão. Augusto de Lacerda, the dramatic critic, also a playwright, his tragic comedy, *O Pastellero De Madrigal* gaining a prize in 1924.

The veteran Henrique Lopes de Mendonça used his qualities as a dramatist and his knowledge of old Portugal in the composition of five stirring tales, *Lanças n' Africa*, *Capa e Espada*, *Fumos da India*, *Santos de Casa* and *Sangue Portugues* (1921-5). The Conde de Sabugosa, Lord Chamberlain under the monarchy, published five volumes of historical studies between 1912 and 1924. To wide reading, made possible by his richly stocked library, and critical ability, he joined imagination and a sense of humour, a combination not very frequent anywhere. His most substantial work is *A Rainha D. Leonor* (1921). He discovered and edited the *Auto da Festa* of Gil Vicente (1525) and the *Auto da natural Invençam* (1550) (Ed. 1917) of Ribeiro Chidao, two real contributions to letters and scholarship. Another *fidalg*o, the Visconde de Santarem, printed the correspondence and re-issued some of the geographical and historical works of his famous namesake, including the *Historia e Theoria das Cortes Geraes* (1924). The Integralist leader Antonio Sardinha (d. 1925) left among other works *A aliança peninsular*, *Ao ritmo da ampulheira* and *Ao principio era o verbo*, the last containing well documented studies on Gen. Gomes Freire, Grand Master of Masonry, executed for conspiracy in 1817, and the unjustly abused D. Carlota Joaquina, wife of King John VI. They throw fresh light on these subjects and the author's conclusions are likely to stand. Other essays of his were, at this time, being reprinted in the review *Nação Portuguesa*. Hippolito Raposo and Manuel Murias belong to the same school. Dr. M. Gonçalves Cerejeira made his name by a work on the Renaissance with versions of the letters of the humanist Cleynarts; his last volume being *A Igreja e o Pensamento Contemporaneo*.

*Historical Works.*—Previous to this period there was no complete history of Portugal worthy of the name, for such as existed were neither impartial, nor the work of men with critical ability and learning. A mass of fresh facts and documents were printed in reviews like the *Arquivo Historico Portugues* and Prof. Fortunato de Almeida used these to compile his *Historia de Portugal*, the third volume of which, carrying the narrative down to 1580, has appeared. The book marks a great advance on its predecessors, covers a wide field and is well supplied with notes. The same scholar published in four stout volumes a *Historia da Igreja em Portugal* (1910, etc.), equally well documented.

The great historian Gama Barros (d. 1925) issued in 1922 the 4th volume of his monumental *Historia da Administração Publica em Portugal nos seculos 12 a 15* and was engaged on a fifth at his death. J. Lucio d'Azevedo, the authority on Pombal, produced an excellent biography of the 17th-century missionary, preacher and diplomat Antonio Vieira, S.J., and the first volume

of his *Cartas* appeared in 1925. D'Azevedo's most notable book is the *Historia dos Christãos novos portugueses* (1922). Edgar Prestage wrote monographs on various embassies of the Restoration period and in collaboration with Pedro de Azevedo undertook the publication of the correspondence of Francisco de Sousa Coutinho, ambassador at The Hague from 1644 to 1650. Vol. 1 came out in 1920. The same editors were publishing the Lisbon parochial Registers of the 16th century. Those of the Church of Sta. Maria do Castello appeared in 1913, and vol. 1 of those of the cathedral in 1924. The statesman João Franco, last minister of King Carlos, issued a number of autograph letters received by him from the King shortly before his tragic death. His political opponents saw in the book a self defence rather than an attempt to set the King's character in its true light and the publication provoked a controversy which is not ended. Affonso de Dornellas in genealogy and history and Antonio Ferrão in the latter have done considerable work.

The *Revista de Historia*, edited by Fidelino de Figueiredo, which suspended publication after the 11th volume, began again to appear, and three new reviews *Lusitania Portugalia* and *Arquivo de Historia*, contain historical articles, but none attempt to fill the place of the excellent *Arquivo Historico*, which came to an end at the 10th volume, on the death of its proprietor and editor Braamcamp Freire. To him we owe an edition of the first part of the *Cronica del Rei D. João I* of Fernão Lopes, a portly volume on the life and dramatic works of Gil Vicente and two learned genealogical tomes on the *Brasões de Cintra*. He was joint editor with D. Carolina Michaëlis de Vasconcellos (d. 1925) of the works of Bernardim Ribeiro and Christovam Falcão. This great Romance scholar issued the 4th of her illuminating *Notas Vicentinas* in 1924, and among her other publications mention must be made of an edition of the *Tragedia de la insigne Reina Isabel* by the Constable D. Pedro. Her husband Joaquim de Vasconcellos edited the *De pintura antiga* of Francisco de Hollanda, the friend of Michael Angelo.

The Lisbon Academy of Sciences was also active; it printed the *Livro da Montaria* of King John I., some dramatic works of the 16th century, the writings of King Pedro V. and vol. 6 of the *Cartas de Albuquerque*. It celebrated the 5th centenary of the capture of Ceuta and the 4th of the death of the great Governor of India by a series including *Alguns ascendentes de Albuquerque* by Antonio Baião, *Documentos das chancelarias reais* by Pedro d'Azevedo, *Marrocos e tres mestres da ordem de Christo* by Vieira Guimarães and by editions of three old chronicles, *Historia de la Ciudad de Ceuta* of D. Jeronymo de Mascarenhas, *Anais de Arzila* and the *Cronica da tomada de Ceuta* of Zurara. This and the *Livro da Montaria* were prepared for the press by Col. J. M. Esteves Pereira (d. 1924), better known abroad as an Ethiopic scholar. His transcriptions of Amharic texts are to be found in the *Boletim da Segunda classe* of the Academy.

The Coimbra University Press, under Dr. Joaquim de Carvalho, author of *Leão Hebreu filosofo*, began to issue reprints of the classics and the following had already come out: *Cancioneiro de Resende*, 5 vol. in 1925, *Historia do descobrimento e conquista da India* of Castanheda, *De rebus Emmanuelis gestis* of Osorio and the *Comentarios* of Albuquerque. The useful *Antologia* of Agostinho de Campos now numbers 20 volumes and contains carefully annotated extracts from Fernão Lopes, João de Barros, Camões, Trancoso, Lucena and some modern authors. The critic Fidelino de Figueiredo established his position as the leading literary historian, and his *Torre de Babel* proves that he can excel also as a essayist, while *Sob a cinza de tedio* shows him as a psychologist. Antonio Sergio published some essays and the *Dispersos* of Oliveira Martins and other posthumous publications include *Sol de Inverno* by the poet Antonio Feijó (d. 1917) and *Figuras de destaque* by the critic Fialho de Almeida (d. 1911).

The invaluable *Revista Lusitana* of Dr. J. Leite de Vasconcellos, which reached its 20th vol. in 1917, continues, and to Dr. J. J. Nunes, the philologist, we owe an edition of the *Cronica dos Frades Menores*; he has also one of the *Cantigas d'Amigo* in the press. The *Anais das Bibliotecas e Arquivos*, is equal, if not superior, to any publication of the kind in Europe.

POSITION FINDER: see RANGE FINDER.

POSTAL SERVICES (see 22.176).—The Universal Postal Union (1874–1914) was formed by the covenant signed at Berne on Oct. 9 1874 and included at the outset all the European countries, as well as the United States and Egypt. The only non-members of the Union at the end of 1925 were the following countries and territories: In Africa, Nigeria and Northern Rhodesia; in Asia, Afghanistan, Arabia, the Malay States of Johore and Trengganu, the Laccadive and Maldiv Islands; and in Oceania, Tonga and the Friendly Islands.

*War Work of the Postal Union.*—It was decided at the Rome congress of 1906 that the next congress of the International Postal Union should be held at Madrid at the end of 1912 or during 1913. It was, however, postponed until Sept. 1914, and was therefore interrupted by the outbreak of the World War.

The War completely dislocated the international postal service, the international exchange of postal matter of all kinds being either interrupted or completely cut off. As an example of the difficulties encountered may be mentioned the special postmarks and labels of all kinds and colours which bore witness to every phase of the conflict.

Among these may be mentioned: "ouvert par l'autorité militaire" (opened by the military authority); "verificato per censura" (verified by censor); "aus militärischen Gründen verzögert" (delayed for military reasons); "zurück; Keine Beförderungsgelegenheit" (return; no communication possible); "retour à l'envoyeur, lieu de destination envahi" (returned to sender; destination invaded); "zone dangereuse. Non distribuable" (impossible to deliver; dangerous area); "livraison impossible à cause de la guerre" (delivery impossible for war reasons); "renvoi par cause de blocus" (returned; blockade); "incendie wagon-poste" (postal wagon burnt); "naufrage" (shipwreck); "evacué" (evacuated); "repatrié" (repatriated); "tué par l'ennemi" (killed in action); "pays récupéré; non encore distribuable" (liberated area; delivery at present impossible).<sup>1</sup>

During the war years the Union maintained indirect contact between the various belligerent countries. It was at the disposal of all the humanitarian missions undertaken for the relief of distress. The Rome congress, in accordance with a recommendation made by the Hague Peace Conference, had decided that postal correspondence, registered letters, postal orders and pre-paid postal parcels concerning prisoners of war should in future enjoy free entry. From the outbreak of hostilities, neutral countries were requested to serve as intermediaries for the transmission of postal matter to prisoners. This service reached enormous proportions. Thus, from the beginning of war to the end of 1919, the Swiss post transported on this service free of charge 714,500,000 postal packets to and from all countries.<sup>2</sup> Similarly, the Swedish post, which worked the prisoners' postal service between Germany on the one side and Russia, Japan and Great Britain on the other, transported 12,500,000 packages in parcel post from 1914 to 1917, and sent on 1,726,000,000 postal orders between 1914 and 1916, to a total value of 21,000,000 Swedish kroner.<sup>3</sup>

Throughout the War the International Union, in its capacity as a neutral organisation, maintained continual contact between the postal administrations of the belligerent countries. As a matter of courtesy also it did its best to send on the innumerable private letters which it received every day. In these troubled

<sup>1</sup> Stefan Strowski: *Postal Marks of the Great War*, Amiens (1925).

<sup>2</sup> If these postal dispatches had been stamped, it would have meant a revenue for Switzerland of 61.8 million francs, and the transport of them occasioned an expenditure of 2.9 million francs. (Cf. the postal service of interned civilians and prisoners of war, in the *Report of the Swiss Federal Council* on its work for 1919: "Postal Administration," pp. 49–55).

<sup>3</sup> After Aug. 1916 the postal order work was entrusted to Switzerland (Cf. the Postal Service and the War in Sweden, in the *Postal Union*, 1916–9).

CHARACTERISTIC EXAMPLES OF POSTERS

(2) German

(3) American

(4) Italian

times the reply-paid system gave excellent results, and was largely used by the public, as will be shown by the following figures:—

| Reply-paid Coupons |           |                   |           |
|--------------------|-----------|-------------------|-----------|
| In 1913 . . . . .  | 798,444   | In 1917 . . . . . | 1,371,486 |
| In 1914 . . . . .  | 854,802   | In 1918 . . . . . | 1,171,200 |
| In 1915 . . . . .  | 1,614,457 | In 1919 . . . . . | 1,116,302 |
| In 1916 . . . . .  | 1,579,826 |                   |           |

Thus the Union was, above all, an institution for the furtherance of peace, and it was impossible that it should disappear in the storm. On the contrary, it came out of the War stronger than ever.

*Postal Developments since the War.*—After the Armistice, postal relations were gradually re-established, and the Madrid congress was able to meet in 1920. The congress had to consider 2,248 proposals.<sup>1</sup> The economic systems of all countries had been entirely transformed, and account had to be taken of the new situation. The world currency crisis which followed the War had not yet been settled, and formed a serious obstacle to the proper working of the international post. The Postal Union took the first step in the re-establishment of sound finance by imposing for its own purposes a stable currency on all nations in the form of the gold franc. Further, the old postal rates were now insufficient to cover the costs of the service, and it became necessary not only to give up the idea of adopting a uniform rate of 10 centimes, as had been proposed at Rome by New Zealand, but to acquiesce in a considerable increase in all existing rates. For several years the administrations of the various countries had been experimenting for their inland post with registering machines for stamping correspondence. The use of these machines was, under certain conditions, extended to the international service.

The enormous improvements introduced into aviation during the War made the aeroplane a very valuable ally of the post.<sup>2</sup> The Madrid congress included the aerial services already established between two or more countries in the category of the extraordinary postal services provided for by the Universal Postal Convention, the conditions of transport of which are regulated by private arrangement between the administrations concerned. The old identity card, which dated from the Lisbon congress, was replaced by a simple and practical card, which was also intended to serve as a certificate for postal operations. Finally, a large number of countries signed a new arrangement which allowed any person who had a current post office account in one of the contracting countries to order transfers to be made from his account to a current post office account in any of the countries concerned. The Madrid congress entrusted the necessary revision of the statutes of the Union to a preparatory committee, which held two sessions, one at Zermatt (from July 29 to Aug. 22 1921), and the second at Nice from March 15 to April 14 1922.

*The Stockholm Congress.*—The Stockholm congress was inaugurated on July 4 1924, and celebrated the jubilee of the Postal Union on Aug. 16. All the members of the Union were represented at the congress except Ecuador, Guatemala, Honduras, Nicaragua and Salvador. The congress was able to reduce transit charges and certain other rates. It authorised the insertion of objects liable to customs duty in packets dispatched at letter rates when the import of such objects by letter is allowed in the country of destination. It made special provisions concerning aerial services, increased the dimensions of postcards and samples and extended the employment of reply-paid coupons. Under specially favourable conditions, which were to be voluntary for the administrations, it facilitated the dispatch of

newspapers, periodicals and books by publishers, together with the exchange of literary and scientific publications between learned institutions.

<sup>1</sup> In certain cases the following rates may be collected: (1) a maritime surtax, which may not exceed 25 centimes per delivery for letters, 5 centimes per postcard and 5 centimes per 50 gr. for other objects. (2) an extraordinary surtax.

<sup>2</sup> The Madrid rates could be lowered to the level of those adopted at Rome.

<sup>3</sup> In this case it was possible to maintain the Washington rate, viz., 25 centimes per 15 gr. or fraction of 15 gr.

This article has been prepared from material supplied by the International Bureau of the Universal Postal Union, Berne. See also the sections on communications in the articles on the various countries. See also the 19 vol. of the *Documents of the Congresses and Conferences of the Universal Postal Union* (Berne); and *Universal Postal Convention, Stockholm, Aug. 28 1924* (London, 1925). **POSTER** (see 22.196).—The designing and use of posters from 1900 to 1914 became increasingly important commercially and a more definite part of the business of advertising. This was especially so in the United States, where a line of demarcation appeared, dividing the small posters issued by book and magazine publishers from the large outdoor posters used by advertisers of various commodities. A few of the outstanding American artists who represented in their work the best American poster design and technique during this period were Edward Penfield, C. B.

<sup>1</sup> At the Rome congress there had been only 798 proposals.

<sup>2</sup> Attempts at the transport of the post by air had been made in 1909 after the crossing of the Channel by Blériot; but the first regular services would seem to have been established in British India in Feb. 1911, on the occasion of the Allahabad Exhibition of Arts and Crafts; then later, in Sept. 1911, in England, as part of the ceremonies connected with the coronation of George V. (cf. Theodore Champion, *Historical and Descriptive Catalogue of Aerial Postage Stamps*, 4th ed. (Paris, 1925); P. G. Heurgren, *The Post in Ancient and Modern Times* (Stockholm, 1925).)

Falls, Louis Fancher, F. N. Abbott, J. C. Leyendecker, Leon Gordon, John E. Sheridan, Adolph Treidler, Robert Wildhack and F. G. Cooper.

Shortly before 1910, and reaching its greatest height immediately before the World War, poster designing in Germany became remarkably active and other countries, especially America, showed for a time considerable readiness to adopt the German poster technique as a predominating one. The principal characteristics of German posters of that period were vigour and massiveness of composition, with correspondingly broad painting and strong masses of colour. Striking and unusual ideas were also characteristic. Of the German poster artists, Ludwig Hohlwein unquestionably occupied the foremost place; other important Germans at that time were Karl Kunst, Bernhard and Gipkens.

In England the poster continued, in a logical development, its earlier types, with, however, no such outstanding names as Pryde and Nicholson ("Beggartaff Brothers"). Aldin, Hassall and Pears exemplify the most characteristic type of English poster until the appearance of the striking posters issued by the London Underground Railways Company. Among artists commissioned to paint these were F. Gregory Brown, E. A. Cox and E. McKnight Kauffer, the last being a young American painter working in England.

In Italy the designing of posters has long been in the hands of brilliant artists, an extensive group of whom were working consistently and fruitfully throughout the period 1900-14. Foremost of these, and a poster artist as conspicuous in Italy as Chéret in France, was A. Hohenstein, a master draughtsman and brilliant technician, equalled in draughtmanship only, perhaps, by Alphonse Mucha. Some of the most essentially artistic posters ever painted are those of Giuseppe Palanti for Verdi, Mascagni and Wagner operas. Collectors recognise also the posters of G. M. Mataloni, N. Dudovitch, L. Metlicovitz, N. Mauzan, L. Caldanzano, M. Mazza, A. Terzi, D. Cambellotti, A. Magrini and G. Chini, all noteworthy contributors to the poster art of Italy. Many of the most notable of Italian poster designers were trained by the old lithograph firm of G. Ricordi, founded so long ago as 1808. The Ricordi firm still produces most of the posters in Italy. Billboards are under municipal ownership and leased to posting companies. Considerable poster talent has been shown in Switzerland for many years past, with recent designs characterised by a great deal of colour. Cardineaux, Hosch, Giacometti and Lauby are among the names of prominent Swiss designers. Billboards are privately owned in Switzerland, unlike the municipally owned boards of Italy, or those of Austria, where the cities own a half-interest.

#### POSTERS IN WAR TIME

With the outbreak of the World War in 1914 posters took on a new significance; as the struggle continued and the War needs became increasingly acute, posters multiplied. Artists as a class proved themselves highly patriotic, and the poster was at once recognised as the greatest available vehicle for nation-wide publicity and appeals for the varied activities connected with carrying on a great war. Due to the conscription system, there was no need of posters to stimulate recruiting in Germany, France or Belgium; but recruiting posters appeared first in England and her Dominions and Colonies, and, later, in America. In England posters were issued by the Ministry of Information, which was added to the Parliamentary Recruiting Committee in 1915. Even in the first stages of the War more than 2,500,000 posters, representing the work of over 100 artists, were posted in the British Is. alone. Among the more important men who contributed were Frank Brangwyn, Bernard Partridge, L. Raven-Hill, Guy Lipscombe and G. Spencer-Pryse.

A certain sequence in the successive waves of posters that swept over the combatant countries was observable. First came the recruiting posters, except where conscription existed; next came the battle-cry to the civilian, calling upon him to subscribe to the loans, one loan after another—posters of which the message became increasingly urgent and imperative. Then, as the War

continued, came the conservation posters and the posters of appeal to aid various organised enterprises engaged in war work. This group comprised food and coal conservation, ship building, hospitals, milk funds, destitute dependent funds, the Red Cross, the Y.M.C.A. and a number of other agencies, activities and needs brought on by the War.

A French War Loan poster that was striking in its conception showed a French poilu in full equipment going forward, with action in every line. He is looking back as he makes the forward charge, flinging out his arm to lend emphasis to his shout: "On les aura!"—"We'll get 'em!"—to the civilians implored to subscribe their share of the loans to win the War. It was the work of Jules Abel Faivre, and one of the most celebrated of all War posters. Another French Loan poster—the work of Georges Scott—shows the heroic allegorical figure of France holding aloft a sword and a battle-scarred flag. Behind her march the poilus with beating drums and a forest of flags. Overhead airplanes are patrolling a War-wracked sky. Four other French Loan posters that attracted attention because of their effectiveness included "The Loan of the Last Cartridges: one more effort, people of France!" It was the work of an anonymous artist and showed an embattled soldier with his face to the enemy, gun in hand, holding out his hand to receive from a civilian and a small child a box of cartridges and a hand grenade. The second of these four French Loan posters showed two figures in the traditional costumes of Alsace and Lorraine awaiting rescue by France. This poster was the work of Auguste Leroux. The third of these four posters, by Faivre, who designed the "We'll get 'em!" poster, is an appeal to the French people, showing a gigantic French gold piece crushing a German soldier, the Gallic cock leaping from the design of the coin to make the attack more spirited. The appeal is "For France: Pour out your Gold; Gold fights for Victory." The fourth poster of this group is the work of Lucien Jonas and shows the American Expeditionary Force, arriving on the run, with the spirit of victory and determination on their faces. In the foreground are soldiers of the three Allies, Italy, France and England. In addition to these, on the roll of honor of France for poster designs, are the names of Steinlen, Newman, Poulbot and Willette.

When the United States entered the War there was at first considerable confusion in that country in the matter of assigning poster commissions, as had been the case in most of the other countries. In April 1917, however, Charles Dana Gibson formed a committee of the most prominent artists and illustrators in and about New York; this committee was soon recognised by the Government in Washington as officially a part of the Division of Public Information. It then became known officially as the Division of Pictorial Publicity and unofficially as "Gibson's Committee."

The method by which the committee functioned was admirably efficient. The committee met regularly each week, and at each meeting Frank D. Casey reported the requests for posters, cartoons, or illustrations received that week from or through the Government as well as from patriotic and charitable organisations throughout the country. Each request was put in charge of a "Captain" who made it his immediate business to see that idea-sketches were received promptly from such artists as were judged best fitted to carry out the assignment. The sketches were then passed through the committee headquarters to Washington, and the finished paintings were made as soon as the sketches were approved. In the course of the committee's work 700 different posters were made for the publicity needs of the Government and for civilian War activities. Among the 187 artists actively enrolled were 33 of the country's most prominent cartoonists. Thirty-seven artists and illustrators devoted their entire work to the needs of the navy, and C. B. Falls specialised almost entirely on the marines. The following names constitute a partial roll of American artists whose work was of special significance in the design of posters during the War: C. D. Gibson, Frank D. Casey, C. B. Falls, Albert Sterner, C. Livingston Bull, Henry Reuterdaahl, August Hutaifi, E. M. Ashe, Henry Raleigh, Walter Whitehead, Charles Sarka, F. G. Cooper, Crawford

Young, John E. Sheridan, Wallace Morgan, George Illian, A. E. Foringer, Harrison Fisher, Howard Chandler Christy, George Wright, F. Walter Taylor, Gordon Grant, W. T. Benda, Edward Penfield and James Montgomery Flagg.

Since the War the poster has naturally resumed its place throughout the world as an active branch of commercial advertising, with certain characteristics worthy of note in the countries where posters are most extensively used. In England the London Underground Railways Co. has continued to produce posters both artistic and effective, by a variety of artists, and commercial posters in general have shown a logical development of their trend before the interruption by the World War. One of the most important series was one done by G. Spencer-Pryse to commemorate the Exhibition at Wembley—a series showing the peoples and industries of the entire British Empire, with its Dominions and Colonies. The most radical departure from pre-War types of poster is to be seen in the "Expressionist" posters of Germany, which are a part of the general radical art movement that affected painting, stage settings and many other art activities in Germany. Grotesque, bizarre, with virtually illegible lettering and with violent vibrations of line and mass, this type of German poster art has not exerted in other countries the influence that characterised the posters of pre-War Germany.

In the United States great strides have recently been made in the development of the poster as an organised advertising medium. Modern business has discarded the old-fashioned "bill-board," with its unkempt appearance and its posters of many sizes. In its place, due to the standards of practice of the Poster Advertising Assn. (now renamed the General Outdoor Advertising Assn. of America) there has come the standard structure, a poster panel 25 ft. long and 12 ft. high which is surrounded by a green moulding as a frame for the poster. The standard commercial poster throughout the United States is the "24-sheet," whose size is 8 ft. 10 in. in height and 19 ft. 8 in. in length. Members of the Association take great pride in the appearance of their structures. When a poster panel is built on the ground green lattice is used to hide the braces and posts. The location is graded and sometimes planted with grass and shrubs. Many of these structures are illuminated at night.

The standards of practice of the Outdoor Advertising Assn. require that members shall not erect poster panels on strictly residential streets, nor in locations where they will mar natural scenic beauty or prove dangerous to traffic. No poster is permitted which shall offend the moral sense of the public or which induces violation of the Constitution of the United States or any laws or ordinances. The almost universal use of automobiles has given a great impetus to poster advertising, and the 24-sheet poster is now being used extensively in the advertisement of a wide variety of commodities.

Since the War there has also been a marked improvement in the general standard of commercial poster art in America. Among the designers of this type of poster are: Clarence Underwood, F. Nelson Abbott, John E. Sheridan, Harry Morse Meyers, Walter Whitehead, J. C. Leyendecker, Norman Rockwell, William Oberhardt, McClelland Barclay, Neysa McMein, Adolph Treidler and Linn Ball. The death of Edward Penfield in 1925 deprived American poster design of one of its most able, conspicuous and significant artists. In the United States poster art and its industry are represented by a monthly publication in colours—*The Poster* which keeps in touch with all developments of poster advertising and poster art. (M. PR.)

**POTTERY:** see CERAMICS.

**POULSEN, VALDEMAR** (1869– ); Danish engineer, was born at Copenhagen Nov. 23 1869. He became an assistant in the technical section of the Copenhagen telephone establishment and in 1898 he invented the telegraphone, an electro-magnetic phonograph capable of registering human speech by the alternating magnetisation of a wire. In 1903 Poulsen invented the Poulsen arc, a generator that produces continuous high tension currents, thus solving one of the greatest problems in the science of radio technique. The Poulsen arcs are used by numerous radio stations throughout the world.

**POUND, ROSCOE** (1870– ); American jurist and educationist, was born at Lincoln, Neb., Oct. 27 1870. He graduated at the University of Nebraska (A.B., 1888, A.M., 1889), and studied law in the Harvard Law School 1889–90. On his admission to the bar in 1890 he commenced practice in Lincoln, Nebraska. He was assistant professor of law at the University of Nebraska, 1899–1903; and dean of the law faculty, 1903–7; was professor of law at Northwestern University 1907–9, and at the University of Chicago, 1909–10. In 1910 he accepted the Story professorship of law at the Harvard Law School, becoming Carter professor of jurisprudence there in 1913, and dean in 1916.

Pound has written *Phytogeography of Nebraska* (with F. E. Clements, 1898); *Readings on the History and System of the Common Law* (1904); *Readings on Roman Law* (1906); *Lectures on the Philosophy of Free-Masonry* (1915); *The Spirit of the Common Law* (1921); *Criminal Justice in the American City* (1922); *Introduction to the Philosophy of Law* (1922); *Interpretation of Legal History* (1923); and *Law and Morals* (1924).

**POWER, SIR WILLIAM TYRONE** (1819–1911), British soldier and administrator (see 22.224), died July 24 1911.

**POYNTER, SIR EDWARD JOHN, BART.** (1836–1919), British painter (see 22.239), died in London July 26 1919. In 1919 he was created K.C.V.O.
